THE ENGINEERING AND MINING JOURNAL

VOLUME LXXXVII, JANUARY TO JUNE, 1909

Illustrated Articles are Designated by an Asterisk (*). Names of Books are indicated by a dagger (†).

A		PAGE		PAGE	
A. K. R. Gold Mfg. Co.	182, 1395	Alaska mine, Calif.	867, 1152	Ammonia, ammonium sulphate.	82, 1051, 1095, 1241
Abbadia San Salvatore mine.	1242	Alaska mining in 1908.	*100, 201, 251	Ammonia cyanide process.	814, 666
Abbotikon, Block I.	196, 427	Alaska, Proposed railroad.	*102	Ammonium persulphate, Etching agent	*1040
Abdulla Mines, Ltd.	1061	Alaska, Silver, in 1908.	54	Amy group, Idaho.	183
Abbot, Frederick A.	1298	Alaska-Treadwell.	101, 1041	Amazonda Cop. Mfg. Co.	
Abbott, R. R. Microstructure of copper.	*1040	Alaska-Yukon-Pacific Expo.	426	59, *106, *215, 265, 474, 522, 562,	
Abel, Sir Frederick.	1085, 1087	Alba Mineral Co.	1021	643, 885, 914, 960, 1200, 1207, 1251	
Abosso mine, West Afr.	196, 427, 905	Alberta, Coal.	565, 579, 623	—Belt coal mine	1153, 1189
Abrasive, Prices in 1908.	82	Albino mine, Colo.	1010	Ammonia mine, Calif.	
Acedia Coal Co.	333	Album for mill products.	796	Anacortes tale mine, Wash.	1308
Accident fund—Coal-mining tax.	220	Algeria, Copper mines.	955	Anderson, C. E. Elec.-driven pumps	998, *1091
Accident, South African colliery.	446	Algonia dist. land opening.	915	Anderson drill.	328
Accidents and Geol. Survey.	29, 81, 196, 212, 446, 558, 762, 823, 951	Alice mine, Idaho.	469	Anderson's drilling experiments.	351
Accidents, Coal-mining, in 1908.	83	Allanite, Value of.	967, 1105, 1152, 1207, 1210, 1301	Andes, Railroad across.	376
Accidents, Colliery—Various countries.	90	Alleghany district, Calif.	*1004, 1147	Andrews, Col. J. A., Death of.	869
Accidents, Colliery, Views on.	12	Allen, A. W. Vacuum filtering.	1019	Anglo-French Exploration Co.	1274
Accidents, Economy as related to.	359	Alliance Coal Co.		Anglo-Siberian Co., Ltd.	650
Accidents, European—Safety lamps, etc.	220	Allis-Chalmers power machinery.		Ankylotomiasis.	314
Accidents, Illinois.	87	Allouez, Mich.	20, *508, 862	Anthracite coal. See "Coal."	
Accidents in coal mines in 1908.	196	Alloys, Aluminum, calcium, etc.	1010, 1079	Anti-Debris. See "Debris." "Dredging."	
Accidents in metal mines, Prevention.	*298	"Alloys and their Industrial Application."	1149	Anti-Japanese tariff.	418
Accidents, Indiana.	88	Alloy, Iron-cerium-lanthanum.	217	Antimony and gold mines, France.	*792
Accidents, Ky., Coal-mining.	1250	"Alloys, Metal."	1374	Antimony and Ore in 1908.	
Accidents, Mine, Prevention of.		Almaden mines, Spain.	453	Antimony, Borneo and Lahaul.	850
Accidents, Montana.	1249, 175, 1198	Alta Montana Cop. Co.	40, 293	Antimony, China.	1276
Accidents, New Mexico.	88, 89	Alum and aluminum sulphate, U. S.	1239	Antimony, Determination of.	497
Accidents, Pennsylvania.	12, 90, 359	Alumina in copper blast furnace slags.	223, 1012	Antimony—Jamesonite ore treatment.	891
Accidents, Transvaal mines.	562	Aluminum and electrical work.	119, 199	Antimony mines of Italy.	844
Accidents, Unusual.		Aluminum coins in France.	11, 607	Apex Underwriters Syndicate.	276
Accidents, West Va.	*1084	Aluminum direct from bauxite.	752	App mine, Calif.	1062
Acetylene lamps for miners.	22	Aluminum in Japan.	1289	Appalachian Engineering Assn.	
Acetylene lamps, underground.	177	Aluminum in 1908.	140, 1005	Appalachian oilfield.	376, 424, 966, 1104
Acheson, Edward G.	317	—U. S. foreign trade.	336	Aquamarines, Brazilian mining.	124
Adair-Usher process in Pachuca.	1390	Aluminum-prices in 1908.	*74	Arboul mill, Queensland.	1092
Adams, Arthur K.	721	Alumina production.	1033, 1095	Arcadian, Mich.	*61, 577, 775, 1020, 1305
Adams, Frank D.	572	Alumite, Determination of.	1122	Ardis, furnace, etc.	168, *1129
Adams, G. I. Submarine petroleum.	913	Amatization.	177, 121	Arens, Waldemar, Death of.	716
Adams, Huntington.	913	Amador Consol. M. & D. Co.	1059	Argall, George O.	1206
Adicks, F. P.	1252	Amador Gold & Cop. Co.	673	Argentum mines, Ltd.	921
Adison's Flat, N. Z., alluvial working.	*198	Amador Mines Co.	1155	Argo works, Secret process at.	464, 963
Adieu-Vat mines, French Guiana.	671	Amalgamated Asbestos Co.	826, 1260, 1308	Arizona, Copper.	56, 58, 103, 907
Adirondack graphite industry.	90	Amalgamated Cop. Co. and properties.		—Jas. Douglas on practice.	1202
Adkinson, Henry M.	225, 572	(See also names "Anaconda," etc.)	*106, 108, 477, 514, 577,	Arizona Cop. Co.	
Adventure, C. Mich.	*62, 525, 918, 1157	—Report.	771, *953, 1020, 1157, 1210, 1251	—Report.	59, 181, 231, 320, 380, 505, 1262
Adve.	173	—Coal properties.	*587, *847	Arizona Copper-Gold Mines Co.	103
Aerolite, Nev. in 1908.	121	Amalgamation and blanketing.	599, 605, 297, 310, 350, 543, 609	Arizona Gold M. & M. Co.	53, 103
Afelder, W. L. Coke-drawing machinery.	510	Amalgamation of Grass Valley.	*439	Arizona, Lead.	104, 763
Africa. See "West," "South," "Transvaal," "Rhodesia," "Rand," "Guinea," "Katanga," "Congo," "Algeria," "Tunis," etc.		Amalgamation of Transvaal mines.	130, 398, 619	Arizona, Mining code for.	1198
Agates, Brazilian mining.	1235	Amalgamation plates. Notes on.	251, 361	Arizona mining in 1908.	59, 103, 213, 372
Agitation, Cyanide lixiviation by.	*695	Amalgam, New.	348	Arizona Power & Water Co.	330
Agitation tanks, Continuous, El Oro.	*683	Amatrice, New gem stone, Utah.	*1038	Arizona, Silver.	54, 59, 103
Agitator-filter, Hendryx.	*842	Amazon, Upper, Auriferous alluvials.	496	Arkansas, Coal.	91, 162, 237, 725
Aguatec mines, Costa Rica.	1022	—Gold dredging.	643	Arkansas Diamond Co.	870
Ablers, F. O. Manganese, India.	955	American Cement Co.	1259	Arkansas, Pike Co., Diamond mine.	
Abweck, Mich.		American Cyanamid Co.	138	Arkansas, Zinc ore.	*152, 371, 616, 963
*60, 279, 477, 1007, 1020, 1157		American Chemical Co.	104	Arsenic mines resumption, Va.	1006
Alka colliery explosion, Hungary.	329	American Chemical Society.	36, 966, 1104	Arsenic tariff.	777
Alm Arco Co., Algeria.	623	American Eagle, S. D.	113, 235, 1060	Arsenic and arsenious acid production.	1090, 1095
Alm, compressed, cutting machine.	*129	American Electrochemical Soc.	868	Arsenic, Rapid estimation.	945
Air, compressed, Raising liquids by.	*646	American Esperanza Mfg. Co. report.	1065	Arsenic, Arsenic.	1090
Air compressors, Buying—Note.	322, 1096	American Fullers' Earth Co.	1065	Arsenic and arsenious acid production.	1090, 1095
Air compressors, Hydraulic, Blakney.	*841	American Iron & Steel Assn.	76, 321, 334, 418, 562, 610, 911,	Artesia, Precious metals used in.	499
Air compressors, Moderate-volume, centrifugal, General Elec.	453	American Inst. Chem. Engineers.	1095, 1114, 1148	Artesia, Mex., Mining in.	700, 963
Air compressors, Turbo, Freytag on.	698	American Inst. Mining Engineers.	815, 1104	Asbestos, Canada.	563, 571, 826, 1260, 1308
Air drying. See also "Dry blast."		—Meeting at Yale.	36, 178, 313, *458	Asbestos, N. C.	224
Air drying for blast furnaces—New patent.	*1242	—Conservation meeting.	515	Asbestos, South Africa.	623
Air economy in rock drills.	*835	—Jas. Douglas' paper.	515, 1202	Asbestos, U. S.	234
Air locomotives, Coupled.	397	American Mining Congress.	520, 923, 820, 968, 1198, 1249	Asbestos, U. S. deposits consolidated.	812
Air testing, Practical methods.	15	American Radiator Co.	614	Asbestos, Wyo.	111, 1016
Air, electricity for coal cutters.	649, 1042	American Smelters Securities Co.	236, 777	Asb Creek Co., Ariz.	103
Alax-Unta Gold Mfg. Co.	718	American Sm. & Ref. Co.	104, 113, 230, 369, 514, 617, 628,	Asb in coke, Estimation of.	899
Alabama, Coal and Coke.		—Statements.	1012, 1016, 1060, 1193, 1267, 1210	Asbanti Goldfields Corp.	197
Alabama Consol. C. & I. Co.	624	—Production in 1908.	366, 417, 419	Asburo Gold Mfg. Co.	1065
Alabama, Gold, in 1908.	53	—Cost, silver-lead smelting.	1007, 1010	Asbworth, J., Opinions of.	266, 1067
Alabama, Iron, in 1908.	189, 321	—Kiln, matte-tapping car.	*1294	Asphalt, Calif., in 1908.	121
Alabama iron market in 1908.	77	American Soc. Engineering Contractors.	913, 1151	Asphalt, Italian.	1096
Alamos and Artaza districts, Mining.	*699, 963	American Soc. Mech. Engineers.	806	Asphalt, Lands, Calif., Disposal.	1233
Alaska Cop. & Coal Co.	964	American Street & Interurban R. R.	840	Asphalt, N. M.	111
Alaska, Copper, in 1908.	56, *100, 907	American Vanadium Co.	906	Asphalt, Nigeria.	1037
Alaska copper—Maps.	*101, 1012	American Zinc, Lead & Smg. Co.	70, 72, 286	"Asphalts: Sources and Utilizations."	*1013
Alaska, Geol. Surv. work in 1908.	211	Amicus-Sylvanite Mines Co.	42	Assay fluxes, Borax in.	696
Alaska, Gold, in 1908.	53, 100, 251	Ami, Henry M.	1300	Assay of gold in copper bullion.	405, 599
Alaska, Interior, Placer gold mining.	591			Assay office, U. S., Salt Lake Cy.	378
"Alaska, Ketchikan and Wrangell Districts."	135			Assays, Crucible.	143
				Assaying silver bullion.	942
				Assaying stamp-mill by-products.	947
				Assessment work—Legal decision.	821
				Assessments, Contland, Penn.	776
				Assets Gold Mfg. Co.	1306
				Associated Oil Co.	93, 573, 606, 811, 1059
				Asten's aneroid barometer.	*258
				Astley, J. W.	1014

	PAGE		PAGE		PAGE
Atchison, Topeka & San P ^e .	160, 1908	Baths for coal miners.	801	Blasting.	See also "Explosive," etc.
Atkinson, A. S., Mica mining.	941	Batopilas M ^g . Co., Mex.	528, 724, 826	Blasting accidents, Economy and	359
—Mining for gems, Brazil.	1234	—Report etc.	912, 1112	Blasting accidents, metal mines, Pre-	299
Atlanta dist., Idaho.	118	Battersby, W. F.	36, 228	Blasting—vention.	84
Atlantic mine, Idaho.	*62, 232, 525	Battery and cyanide costs.	890	Blasting—Blow-out shots.	84
Atlantic mine, Mich.	619	Bear Creek Coal Co.	*845, *848	Blasting—Coal-dust question, Eng.	1290
Atlas bottom-delivery electric cable	619	Bear Gulch Placer M ^g . Co.	918	Blasting—Elec. shot firing by Utah	1190
Auriferous alluvials, upper Amazon.	496, 643	Beard, J. T., on explosions.	1259	Blasting—Fuse-spitter suggestion.	813
Aurora mine, B. C.	527, 1111	Beardsley, G. F., Alumina in slugs.	223, 1012	Blasting notes.	
Australasia, Coal.	126, 887	Beasley, N. B., Salt production with exhaust steam.	1150	180, 219, 212, 220, 246, 314, 766,	
Australasia Copper.		Beaver mine, Ont.	778, 1112, 1209, 1214, 1255	415, 652, 512, 560, 612, 648, 762,	
Australasia, Gold.	814, 681, 764, 852, 907	Beaver Carbonate mine, Utah.	873, 973, 1111	70, 352, 1006, 1052, 1096	
Australasia, Iron ore deposits.	349	Beck Tunnel, Utah.		Blasting powder, Mfr., by miners.	*812
Australasia, Lead.	123	Bedding system, Cannanea Consol.	723	Blasting reports, Mont. coal mine.	*848
Australasia mining in 1908.	123	Beeler, Henry C.	60	Blasting—Jamming shot holes.	813
Australasia, Silver.	123, 297, 565	—Wyming mining.	111	Blasting tests, Geol. Surv.	
Australasia, Tin.		Belcher mine, Colo.	106	23, 196, 212, 446, 1190	
125, 423, 468, 652, 902, 1280		Belcher Silver M ^g . Co.	494	Blasting—Views on explosions.	12
Discoveries, Pine creek.	1272, 911	Belgium, Accidents with Explosives.	*1013	Blasting—Windy shots.	965
Australasia, Zinc.	68, 124, 265	Belgium, Coal-mining accidents.	90	Blaugas Co. of America.	461
Australasian mineral leasing.	1133, 1048	Belgium, Coal.	386, 482	Bleeders, Adolf, & Co.	*391
Australia—Queensland mining.	*603, *635, *746, *802, *838, 1092, *1125	Belgium, Iron.	1098, *1221	Bliss, Fred G., suit.	1148
Australia, Western, Dividends.	29	Belgium, Miners' pensions.	311	Bloomer, G. R., Alamos and Arizana	1260
Australia, Western, Gold, Nov.	29	Belgium, Spelter, in 1908.	265	dist.	*699, 963
Australia, Western—Tin and gold—		Bell, R. N., Idaho in 1908.	*115	Blower, Rotary, in smelting works.	*532
State mills.	69, 218	Bellmeir mines, France.	*792	Blowing engines, Gas, at Gary.	20
Australian collieries, Electricity in.	317	Bellmont, Tonopah. See "Tonopah."		Blow-out shots.	84
Australian iron boundaries.	611	Belmont.		Blown-out shots and miners' negligence	12
Australian shale-oil industry.	1051	Belt mine, Mont.	*587	cause many explosions.	18
Austria, Coal-mining accidents.	90	Belts, Balata.		Blue Bell mine, B. C.	248, 249, 250
Austria, Coal.	630, 784	Benedict—Saddle reefs; temperature.	323, 348, 560	Blue Bell mine, Nev.	285
Austria-Hungary, Copper.	981, 907	Benedict, C. H.	770	"Blue gas," German illuminant.	465, 965
Austria-Hungary, Iron.	1098	Benedict fund, coal-miners' families.	570	Blue Lead mine, Calif.	277
Austria, Salt.	1091	Bengal coal-mining industry.	*555, 558	Bluejacket strike, Okla.	1110
Austria, Spelter, in 1908.	265	Bangladesh Railway.	88, 407	Bluestone M ^g , by miners.	120
Austria, 9-hour law.	1052	Bennetts, R. H., Magnetite treatment	962	Bluestone M ^g , Salome, Calif.	1239
Austrian mines, Rescue apparatus.	414	in copper blast furnace.	962	Boeck's new flash suit.	*486
Austrian petroleum agreement.	1112	Benson mine, Calif.	39, 428	Bogardus, C. E.	869
Autonite.	257	"Berechnung und Untersuchung des		Boilers, Burning wood under.	1096
Awanya, Ikeda & Co.	1159, 1213	Eisenachthausens."	815	Boilers, No pressure, rust.	1091
		Berger's tin assay method.	651	Bolesworthy, W. E., Sectional gin	*817
		Berlin as gold market.	518	poles.	127, 826
		Berry mine, Maine.	1129	Boleo mines, Lower Calif.	861
		Bertina zinc mines, Va.	1011	Boleo, Compagnie de.	681, 907
		Berwind-White Coal Co.	964	Bolvila, Copper.	240
		Beryl, Maine.	1127	Bolvila, Tin-ore arrivals from.	*833
		"Beryllium, Chemistry and Literature."	*1013	Bonanza creek, Yukon, Dredge on.	819
		Beskow, K. I., Meyer's tangential	1033	Bonanza mines, Guggenheims.	964, 1139
		Betta process.	327	Bonanza claim—Harrison Gulch case.	717
		Bessemer Coal, Iron & Land Co.	*1081	Bonanza King, Sierra co., Calif.	1152
		Bessemerizing copper.	780	Bonanza King, Trinity co., Calif.	790
		Bethlehem Steel Co.	*653	Bonney on eclogite nodules.	1307
		Bethune, Compagnie des Mines de	891, 822	Bonnie Clare M. & Co.	229, 872, 1307
		Bewick, Moreing & Co.	372	Bonsall claims, Ont.	432, 874
		Bichel, Prof., on coal dust.	952	Boorman, T. H., "Asphalts."	*1013
		Biermann, Henry, Death of.	669	—Bitumen and oils, West Africa.	1037
		Big Four R. R. Co.	1016	Borax hauling with string teams.	678
		Big Mitt mine, Utah.	431	Borax in assay fluxes.	1096
		Big Six, Ont.	43	Borax in 1908.	82, 121, 137
		"Big Vein" coal seam, Working.	*303	Borax, Platinum in.	1232
		Big Vein Pochontas Coal Co.	777, 1021	Borax Properties, Ltd.	108
		Biglow, A. S.	514, 523, 533	Bore-hole, Surveying apparatus.	*854
		Bighorn basin coalfields.	163	Bore-hole, Oil extraction from.	*1001
		Big Steel, Davis Colliery Co.'s.	*1287	Boring. See also "Drill," etc.	
		Bins, Measurement of contents.	641	Boring machine, Tunnel, Terry, Tench	*1296
		Bingham amalgamated Co.	281	—& Proctor, Fracture test.	181
		Bingham-Burke, Utah.	186	Boring machines, Rocky Tunnel.	256
		Bingham Metals M ^g . Co.	378	Boston coal receipts in 1908.	123
		Bingham Mines Co.	378, 920	Roston Consol.	
		Bingham, Utah, map.	114	113, *114, 235, 275, 479, 771, 859, 1060,	
		Birdsboro Steel Pdy. Mach. Co.	619	—Report.	760
		Birkeland-Eyde nitrate industry.	620	Boston & Montana.	108
		Birmingham Coal & Iron Co.	50, *106, 275, *408, 718, 867,	Boston & Corbin.	
		Blasbe Conditon M ^g . Co.	327, 380, 505, 896, 899	59, 1029, 1257	
		Bishop, J., & Co.	1010	—50-ft. chimney, G. Falls, *156, *223, 1391	
		Bishop, L. D., Notes on cyanidation.	*842	Rotsford, W. W. Geol. Gunnajuato	
		Blismarckhütte elec. steel process.	1147	dist.	*691
		Bismuth.	151, 1095	—Zacatecas dist. and relations.	1089
		Bismuth, copper and nitric acid.	938	Bitecans gas field.	1095
		Bismuth-ore tariff.	609	Bondard, O. J., Coal oxidation.	995
		Bits for drills, Selection and use.	*1183	Boulder co., Colo., tungsten field.	*1055
		Bitumen and oils, West Africa.	1037	Boudard-Gordou claim, Gouganda.	901
		Bituminous coal. See also "Coal."		Boyer Nevada Cop. Co.	1014
		Bittum Coal & Coke Co.	*845	Boyle, Emmet	1014
		Bixby's, Perry, mine, Calif.	1301	Bradley, C. S.—New process	1054, 1212, 1245
		Black Eagle flats, Mont.	*408	Bradley, Geo. W.	716
		Black Hills, New smelter for.	675	Bradshaw lease, Rawhide, Nev.	184
		Black Hills Porcelain, Clay, etc. Co.	975	Brainerd, Frederick H.	376
		Black, Nell, Death of.	770	Brakpan mines, Transvaal.	130, 559
		Black, W. D., Topographic engi-	997	Branch Mnt. S. D.	113, 331, 422
		—neering.		Brand, J. F., Sand boils.	757
		Blackbutte, Ore., Dennis furnace.	141, 235	Brandes, J. Ann	818
		Black Hole mine, Nev.	41	—diamond bearing highlands, Bahia.	*981, *1029
		Blaisdell Co., Adair L. Sher process.	317	—	868, 968
		Blake, William P.	1306	Brazil Block Coal Co.	
		—Arizona mining.	103	Brazil Bahia Diamonds, manganese,	
		Blake & Knowles pump.	*219	copper, gold, salt, salt-peter, pig-	
		Blakey hydraulic air compressor.	*500	ments, marble, limestone, mica, etc.	
		Blanc turbo-classifier.	472	*881, *1029	
		Blanchard, J. H., Death of.	472	Brazil, Diamantina district.	856
		Blanketing, etc., Notes on.	609	Brazil, Mining for gems.	1284
		Blanketing, 259, 265, 297, 310, 350, 543, 609		Brazilian monazite.	781
		Blanketing, Giant mine, Rhodesia.	259	Breathing. See also "Rescue"	
		Blast. See "Furnace," "Dry," etc.		Breathing apparatus, Austrian mines.	414
		Blast holes, Loading.	225	Breathing apparatus, Indiana	762, 823

VOL. LXXXVII.

NEW YORK, JANUARY 2, 1909.

NO. 1.

Iron Operations in the Chattanooga District

General Conditions Are Similar to Those of Birmingham District; Two of Largest Operating Companies Have Raw Materials close to Furnaces

BY EDWIN HIGGINS

For convenience the Chattanooga district may be said to include the territory 70 miles northeasterly, and 30 miles southwesterly, from Chattanooga, its width varying from 20 to 30 miles. This includes Roane, Rhea and Hamilton, and parts of Morgan, Cumberland, Meigs and James counties, Tennessee; parts of Jackson and De Kalb counties, Alabama, and parts of Dade, Walker and Chattooga counties, Georgia. The southern boundary of the district is not well defined, the

\$1 per ton, and the cost of producing iron is not much in excess of \$10 per ton. Foundry iron is the chief product of the furnaces.

The present production of pig iron amounts to about 25,000 tons per month. This is divided as follows: Roane Iron Company, 12,000 tons; Dayton Coal and Iron Company, Limited, 9,000 tons; Citico Furnace Company, 4,000 tons. The furnaces of the Southern Steel Company, now in bankruptcy, at Battelle, Ala., Chat-

tanooga, which are typical of the practice in the Chattanooga district, will be described. This company owns extensive ore and coal lands and limestone deposits in the immediate vicinity of Rockwood, Roane county, at which point the blast-furnace plant is situated. Two stacks are now in blast. Included in the ore lands are important deposits about 10 miles southeasterly from Rockwood and south of the Tennessee river. The map, Fig. 2, embraces the territory covered by the opera-

FIG. 1. STRIPPING AT CHAMBERLAIN, OR WELKER, MINE; ORE EXPOSED AT THE SIDES AND AT THE FACE

iron industry here being more or less intimately connected with that of the northeastern Alabama district.

The Clinton formation, including shales, sandstones and limestones, outcrops at various points north of Chattanooga in the vicinity of the Tennessee valley, and to the south along the northwest slope of Lookout mountain.

As in the Birmingham district, raw materials are found within a radius of a few miles, and conditions generally favor the production of pig iron at a low cost. The cost of mining the ore seldom exceeds

nooga, Tenn., and Rising Fawn, Ga., are not in operation.

Toward the close of 1908 only a slight improvement was noticeable in the iron industry of the district. However, there is promise of better times after the first of the year. The demand for iron has shown a gradual increase and this district, in common with the southern field generally, has felt the demand to a greater extent than the iron districts of the north.

ROANE IRON COMPANY

The operations of the Roane Iron Com-

pany. Extending diagonally across the map is a geological section of the country from Waldens ridge through the ore mines in the vicinity of Welker.

The total output of the company's mines is from 1000 to 1100 tons of ore per day, from which there is made from 300 to 350 tons of pig iron per day. With respect to the centralization of the source of supply of ore, coal and limestone, conditions are most favorable for the manufacture of pig iron at low cost.

ROCKWOOD OREBED

The company obtains most of its ore (from 700 to 800 tons per day) from the Rockwood vein, which outcrops at the foot of Waldens ridge, as shown in Fig. 2. This orebed strikes northeasterly and southwesterly, and has an average dip of 30 deg. toward the northwest. The most productive part of the bed is included within a length of about 4 miles, the width of the ore varying from 30 in. to 4 ft. The ore has the following range of composition: Iron, 37 to 40 per cent.; silica, 5 to 8; lime, 10 to 17; alumina, 3 to

plays 40 men and produces 90 tons per day. Prospect slope is 400 ft. in length, employs 30 men and produces 50 tons of ore per day. Evans slope is 500 ft. in length, employs 20 men and produces 30 tons per day. Clymer slope is 400 ft. in length, employs 15 men and produces 30 tons per day. In Fig. 5 is shown the tippie at one of the slopes near Rockwood. Fig. 6 shows the surface plant.

These slopes are 6x5x7 ft. high; they are all equipped with steam-hoisting plants of capacities varying from 70 to 90 h.p. The amount of water made

100 to 200 ft.; a parting here formed the north and south end of the lift. Recently, however, owing to the harder nature of the south slate, it has been found more permanent to drive the slope under the ore, although the first expense by this method is greater. Entries are driven at 100-ft. centers. On the entries, airways, or rooms, are turned up to the lift above about every 30 ft., leaving a pillar of 20 ft. between the rooms. One 15-ft. pillar is left standing half-way between lifts, and pillars 10 to 20 ft. thick are left under the lifts, being broken only by small air-

FIG. 2

6; magnesia, 2 to 4; sulphur, about 0.2; manganese, 0.1 to 0.2; phosphorus, 0.5 to 0.7.

SLOPES IN OPERATION

There are eight slopes, all situated in the vicinity of Cardiff, now in operation. Mining is done under contract by the Brown Mining Company. The Baker slope is 800 ft. in length; here 90 men are employed and the output is 175 tons of ore per day. Cardiff slope is 1000 ft. in length, employs 75 men and produces 150 tons per day. Carter slope is 1200 ft. in length, employs 40 men and produces 75 tons per day. Patton slope is 800 ft. in length, employs 60 men and produces 100 tons per day. Wright slope is 600 ft. in length, em-

is not large and in most cases is handled by a Knowles pump with 4-in. discharge for the first lift, and one of 2-in. discharge for the second lift. Ventilation is supplied by Cole fans of varying sizes, depending upon requirements. One shift of 10 hours is worked per day. The cost of mining varies, depending upon the nature of the ground, but may be said to be in the neighborhood of \$1 per ton.

GENERAL DEVELOPMENT AND MINING METHODS

The ore was originally worked by driving the slope down to the top slate (known as the north slate) at the angle of dip. Lifts, or entries, were turned off to the ore from this slope at distances of from

holes driven through. Most of the ore is robbed from these pillars on returning.

IRON-ORE MINES SOUTH OF THE TENNESSEE RIVER

The company's ore land south of the Tennessee river lies in two tracts about 4 miles apart. Chamberlain, or Welker, mines (Fig. 2) are the only ones being worked to any great extent. These mines are producing about 200 tons per day of soft brown fossil ore and 100 tons of hard brown fossil ore. The soft ore has about the following average composition: Iron, 47.9 per cent.; silica, 12.10; alumina, 6.27; lime, trace; phosphorus, 0.53; manganese, 0.32. The hard ore shows the following analysis: Iron, 25.20 per cent.; silica, 3.48;

alumina, 3.25; lime, 25.20; phosphorus, 0.32; manganese, 0.15.

Here the orebed occurs in the form of a trough as may be noted in the geological section, Fig. 2. Most of the ore comes from the south end, or "upright," which is worked by driving adits from both sides of the hills until they meet; then the ore

Texas Pacific Railroad, going thence to the furnace at Rockwood. Fig. 7 shows two of these barges loaded with two ore cars and a passenger train. Each barge is laid with a double track and has a capacity of four carloads of ore. This passenger train is the special which left Chattanooga October 5, 1908, carrying the

ment. The bulk of the coal is mined from slopes directly behind the furnace stacks at Rockwood. Here the seam lies in the form of a large trough, pitching into the mountain in a northerly direction. The slope is driven in the bottom of this trough on an average grade of 14 per cent. Entries are driven to right and left of the slope with sufficient grade to allow for drainage toward the slope. Where the coal shows sufficient thickness to be mined, rooms are turned right and left on such grades as to allow mule haulage. The bed varies from a few inches to 30 ft. in thickness, its average being about $4\frac{1}{2}$ ft. Although nearly the whole area developed is more or less disturbed, practically all coal over 3 ft. is worked. As depth is gained under the mountain the bed becomes more level and more regular, but even here squeezes are common.

For some time ventilation at this mine gave trouble, owing to leaks through old rooms, defective brattices and fallen air courses. The mine is dry and requires regular sprinkling to lay the dust. The coal is gaseous and the workings require careful inspection. The rolls and squeezes which characterize the bed sometimes cause the shooting down of large quantities of slate in the entry work.

FIG. 3. A CLOSER VIEW OF THE OREBED AT CHAMBERLAIN MINE

is stoped down to the country below. There are 14 openings on the "upright."

On the north side the ore rises from the syncline on a dip of about 10 deg. The ore is stripped along the outcrop until the overburden attains a thickness of about 30 ft.; eventually, underground mining will be carried on here. This orebed, shown in Fig. 1, is about 8 ft. in thickness, and has a parting near the center of from 10 to 15 in. of slate. Fig. 3 is a closer view of the orebed, taken a short distance back of the work shown in Fig. 1.

The change from the soft to the hard ore occurs just below or at the permanent ground-water level, which in most cases is very close to the surface at the foot of the ridges. A striking example of the change is given in the stripping operation. In Fig. 1 the ore on the left-hand side of the cut is soft on top, grading into a semi-hard near the bottom. On the right-hand side, which is only a few feet lower, the ore is practically all hard.

At present about 150 men are worked at these mines. The cost of production is less than \$1 per ton. The method of transporting the ore to Rockwood is interesting. The ore from the different openings is trammed to tipples and dumped into railway cars; the tipples are from 1 to 4 miles from the landing near Round Island. These cars are hauled over the railroad of the Roane Iron Company to the river, where they are loaded onto barges, and towed down the river a distance of about 8 miles to Hood's Landing. Here they pass onto the tracks of the Tennessee branch of the Cincinnati, New Orleans &

FIG. 4. LIMESTONE QUARRY AT ROCKWOOD

members and guests of the American Institute of Mining Engineers on their visit to the operations of the Roane company. The boat which tows these barges is a shallow draft stern-wheeler.

COAL AND LIMESTONE

The Roane company owns about 8000 acres of coal lands along Waldens ridge, of which 2000 acres are under develop-

The coal is bituminous and has the following average composition (washed): Volatile matter, 31.07 per cent.; fixed carbon, 59.66; ash, 9.27; sulphur, 0.50. Coke from the washed coal shows the following average composition: Volatile matter, 2.59 per cent.; fixed carbon, 83.69; ash, 13.73; sulphur, 0.56. This is an excellent grade of coke for blast-furnace work. The company has in

operation at Rockwood 350 coke ovens of the bee-hive type. The coke ovens are shown in Fig. 9. The furnaces appear in the background.

The principal limestone quarries of the company are situated about $1\frac{1}{4}$ miles southwest of the furnace, and are reached by a narrow-gage railroad. The supply of rock is practically inexhaustible. Following is the average composition: Silica, 1.94 per cent.; iron and alumina, 2.20;

Each furnace makes from 150 to 175 tons of pig iron per day of the following analysis: Silicon, 1.50 to 3.50 per cent.; phosphorus, 1.35 to 1.50; manganese, 0.50; sulphur, 0.02 to 0.05. The furnace plant is shown in Figs. 8 and 9.

DAYTON COAL AND IRON COMPANY,
LIMITED.

The furnaces of the Dayton Coal and Iron Company, Limited, are situated at

in Rhea county. The company has 367 coke ovens at Dayton.

CITICO FURNACE COMPANY

The Citico Furnace Company operates one stack at Chattanooga. The plant consists essentially of one furnace, 69 ft. high, 17 ft. bosh and 10 ft. hearth; three 350-h.p. engines; and four Whitwell stoves. The hoist is vertical and the furnace is hand-filled. The pig is handled

FIG. 5. TIPPLE AT IRON-ORE MINE NEAR ROCKWOOD

FIG. 6. SURFACE PLANT AT IRON-ORE MINE NEAR ROCKWOOD

FIG. 7. TRAIN LOADED ON BARGES AND TOWED BY A SHALLOW-DRAFT STERN-WHEEL STEAMER

lime, 51.70; magnesia, 1.61. Fig. 4 shows one of the quarrying operations.

FURNACE PLANT

The furnace plant of the Roane company, situated at Rockwood, consists essentially of 2 modern blast furnaces, 17x80 ft., equipped with skip hoist and modified Walter Kennedy top; 6 Macbeth blowing engines; 8 Kennedy hot-blast stoves; and boiler plant. Haulage from bins to skips is done with 4 trains of 5 side-dump cars operated with endless cable drive.

the town of Dayton, Rhea county. Here there are two stacks, 75x17½ ft., one of which is being run to full capacity. The output is about 4500 tons of foundry pig per month.

This furnace is running on Georgia brown ores and Tennessee red fossil ores. The company owns 34,000 acres of coal and iron land, the iron being in Meigs county and the coal in Rhea county.

The ores used are nearly self-fluxing; what flux is needed is quarried from the Bangor limestone deposits back of the furnace. Coal is mined near the furnaces

from the casting house by a cradle of 1 ton capacity. This cradle deposits its load on a platform outside of the casting house, whence it is loaded into cars. The output is about 4000 tons of foundry iron per month. The furnace is shown in Fig. 10.

This furnace is running chiefly on custom ores, consisting of brown and red hematites. It has one red-ore mine at Citico, Ala., about 6 miles from Gadsden, on the Chattanooga Southern Railway. This mine is now under development and will soon be ready to produce a considerable tonnage. The ore has the

following composition: Iron, 40 per cent.; silica, 16; manganese, 14. The figure for phosphorus was not ascertained. Some of the ore used comes from the Tecumseh Iron Company, at Tecumseh, Ala., and from the Etowah Development Company,

Queen and Crescent Railway. This is the same flux as that used at the Dayton furnace. Coke is obtained chiefly from the ovens of the New Soddy Coal Company and the Fox Coal Company, about 20 miles north of Chattanooga. The small

and red ores used a mixture which is almost self-fluxing.

When a shaft is sunk deeper than 600 ft. the Victoria, Australia, mining law requires that one compartment, having an

FIG. 8. FURNACES AT ROCKWOOD

FIG. 9. COKE OVENS AND FURNACES AT ROCKWOOD

with mines at Emerson, Ga. Some ore is also shipped in from Attalla, Ala.

The limestone used comes from a point about 18 miles from Chattanooga on the

balance required comes from Virginia and points west of Chattanooga in Tennessee. At this furnace little flux is required, it being possible to make from the brown

area of at least 10 sq.ft., must be partitioned off and used only for purposes of ventilation, being kept clear of ladders, platforms and pipes.

The Broken Hill Proprietary Company

SPECIAL CORRESPONDENCE

This company, the head office of which is at Melbourne, Victoria, was formed in 1885 to work the well known silver-lead deposit of Broken Hill on the Barrier range, New South Wales. The capital of the company has been increased since the original issue and now stands at £384,000 in 960,000 shares of 8s. each, fully paid up. The report for the half-year ended May. 31, 1908, has recently been issued. It contains a detailed account, both technical and financial, of the operations and is accompanied with useful tables showing the fluctuations in the prices of the mine products—silver, lead, zinc and copper—for some years past, as well as plans of

to the financial position of the undertakings they direct.

The most important event in the period under review was the completion of the first unit of a spelter plant at Port Pirie. The first trials have been satisfactory, and the directors have decided to erect a plant capable of producing 8000 tons of spelter yearly, at an estimated cost of £100,000.

The sales of the company's products in the East are expanding. For the half-year ended Nov. 30, 1906, the sale of lead to India, China and Japan amounted to 4537 tons, while for the six months ending May 31, 1908, the sale was 9777 tons. The total sales for the six months were 35,085 tons, of which 21,486 tons went to Europe and 3822 tons were sold to Australia and New Zealand.

Experiments have been made with the Carmichael-Bradford process for roasting

ver, 796 oz. fine gold, 36,140 tons soft lead and 335 tons antimonial lead. The doré plant treated 28,610 oz. doré bullion producing 796 oz. gold. As a result of a visit to America, the general manager, Mr. Delprat, erected a small experimental bag-house for filtering the smoke going to the stack. It has been found that the losses of lead in this direction had been considerable. The experiments have been encouraging and a bag plant estimated to cost £3500 is to be erected. The material gathered in the bags is chiefly sulphide of lead, which burns readily into a well sintered product, containing about 70 per cent. lead and practically no silver.

Owing to the low price of metals, the company's operation resulted in only the small net profit of £22,776 as compared with £137,642 for the previous half-year. The price of lead averaged £12 tos. 11d. per ton and silver 27.9375d. The low price of metals and the small profits earned call for a revision of the rate of wages. The present agreement with the workers expires on Dec. 31 next, and unless the metal markets improve before that date a reduction in the rate of wages will probably be demanded.

As regards the ore-dressing mills it is only necessary to remark that the use of tube mills for re-grinding is extending. Two tube mills of an improved pattern, with four Wilfley tables, have been installed, and two more are in course of erection, while eight additional mills with further improvements are shortly expected from Europe.

The centrifugal pumps for raising slimes, tailings and water are being replaced by bucket elevators, a considerable saving in power and repairs being thereby effected.

The ore-dressing mills treated 262,165 tons of crude ore during the six months. As regards the mine the position is reported to be satisfactory. The deepest level—1400 ft.—has been opened up, the orebody showing at first 6 ft. of fair ore, but at a point 50 ft. to the north it suddenly widened out to 44 ft. of high-grade sulphide ore. The bottom levels—1300 and 1400 ft.—have not yet been systematically sampled, but bulk samples indicate an average value of 16.18 per cent. zinc, 20 per cent. lead and 14 oz. silver.

Part of the mine is still on fire, but the fire is, however, at present well under control, and the directors consider that no serious apprehension need be felt that any interference with the general work of the mine can take place. The expenditure on account of the fire has amounted to £40,000 in all.

The fortunes of the company are dependent, of course, on the prices of zinc, lead and silver. With lead at £13 per ton and silver at 20d. per oz., it is not possible to cover working expenses under present conditions. A revival in the world's trade is required for the prosperity of the company.

FIG. 10. FURNACE OF CITICO IRON COMPANY, CHATTANOOGA

the workings and photographs of the new engineering workshop of the Carmichael-Bradford desulphurizing plant and of the new spelter furnace. Besides the usual auditors' certificate, the accounts are further indorsed by a certificate, signed by the secretary, which is required by the Australian companies act. This sworn certificate gives particulars as to the capital of the company, stating how much of the share capital is paper and how much has been actually paid up in money. A detailed list of the assets and liabilities is also included, together with particulars of the investments securing the reserve and insurance funds. The names, addresses and occupation of the directors are also stated in full. The compulsory publication in Australia of so much explanatory detail, as regards the accounts and the financial position generally, is a practice that might be followed with advantage to shareholders by the directors of many mining companies in England and the United States, who often issue reports which contain but meager information as

concentrates, on different lines from experiments made in former years. A new plant has been put up at a cost of £3300, capable of dealing with 200 to 250 tons a day. A feature of this plant is that, instead of using coal, the only combustible material used is straw, at the rate of about 10 lb. straw to one ton of concentrates. The Port Pirie smelting works carried on operations with nine furnaces. Three of the furnaces have been rebuilt in order to raise the water-jackets, a step made necessary by the more intense blast from the turbo-blower. The tonnage treated was as follows:

	Tons Treated.	Per-centage.
Kaolin and silicious ores (including purchased ores)	10,968	10.02
Sulphide concentrates and slimes	72,195	65.94
Sintered slimes	26,319	24.04
Total	109,482	100.00

In addition there were re-treated 5784 tons of flue-dust and refinery dross.

The refinery dealt with 37,133 tons of bullion, producing 2,102,559 oz. fine sil-

S. Pearson & Son's Uncontrollable Oil Gusher

San Diego de la Mar Well No. 3, near Dos Bocas, Which Burned for Nearly Two Months and Defeated All Efforts to Save the Oil

SPECIAL CORRESPONDENCE

During last summer press despatches in the newspapers reported the progress of a series of attempts on the part of S. Pearson & Son to gain control of a remarkable burning oil well opened near Dos Bocas, Mexico, in one of the extensive operations of that firm. When news came on Sept. 1 that the fire had been extinguished, it was generally supposed that the company's engi-

Mexico by a narrow strip of land less than a mile in width. The subsoil rights to the lands were leased in 1901 by the Pennsylvania Oil Company, of Mexico, an American company, and a well was drilled on the property at a point on the lagoon known as Dos Bocas, but without result. In 1907 the English firm of S. Pearson & Son, Ltd., acquired the controlling interest in the Pennsylvania Oil Company, of

had been encountered in this same well, and he continued to "make hole." After having made about 3 ft. in this formation the internal pressure began to exert itself, coming back through the 4-in. drill stem and bursting the hose. When this happened the driller remained at his post, raising the stem a considerable distance in the well, thinking that possibly it might be only a gas blowout and would soon be

LOOKING FROM THE HIGHEST POINT ON THE EDGE OF THE CRATER TOWARD THE OUTLET. DISTURBANCE NEAR OPPOSITE SHORE ON THE LEFT, CAUSED BY FLOW FROM THE WELL

neers with the aid of a battalion of troops supplied by the Mexican government had gained control of the well; the force of the gusher was then far from exhausted. The violence of the outflow continued to increase until on Nov. 1, when all efforts to save the oil had to be abandoned.

The San Diego de la Mar property is situated in the northern part of the State of Vera Cruz, about 75 miles by water from Tampico, on the Tamiagua lagoon. The lagoon is separated from the Gulf of

Mexico. The first well drilled on the estate by the Pearsons came in at 2005 ft., with an estimated production of 5000 bbl. of oil daily.

San Diego well No. 3, the second well drilled by the Pearsons, came in on July 4, 1908, at a depth of 1824 ft. The drilling for some time prior to the blowout had been in the hard marl, when all at once it passed into soft shale. This created no surprise on the part of the driller, as similar soft shale formations

over. It gradually became stronger, however, and within 15 to 20 minutes the well was flowing at the rate of about 12,000 bbl. daily, causing the ground round the well to tremble considerably and to open up in several places. One of these fissures was immediately underneath the boiler, having started by first throwing out gas and then coming in oil. The fissure suddenly burst into flame, the fire working its way toward the well. A strong breeze was blowing, which made it

impossible for the men to get between the boiler and the well. The fire ignited the gas coming from the well, and simultaneously the whole country surrounding the well was enveloped in a mass of flames. The flow of the well increased in strength and volume until it was making between 75,000 and 100,000 bbl. of oil daily.

EFFECTS OF THE BLOWOUT

At the time of the blowout there were 43 ft. of 11½-in. casing and 1283 ft. of 8-in. casing in the hole. About half an hour after the well caught fire the pressure increased to such an extent that the drill stem was blown out of the hole, through the top of the derrick, to a height of 150 ft., where it bent over like a piece of rubber tube and fell to the ground. The whole 1825 ft. of 4-in. drill stem was blown entirely out of the well.

On July 13, nine days after the fire started, the height of the flames was estimated by engineers to be 1500 ft. At a height of 800 ft. the flames were 90 ft. wide, all of the oil being consumed in the flames. The fire could be seen 200 miles at sea from the Gulf of Mexico. At night a newspaper could be read by the light of the fire 20 miles away. The noise of the fire was rather muffled, somewhat like the roar of Niagara falls. Monster volumes of black oil vapor or smoke would be picked up and rolled over and over again in the flames up to 1500 ft. and more into the air. When it was gushing at its strongest the well was making more than 100,000 bbl. of oil daily.

EXTINGUISHING THE FIRE

The first plan decided upon for extinguishing the fire involved the use of a drag made of the heaviest plates of a 2000-bbl. steel tank, riveted together and weighted down with 30 tons of rails, this to be dragged over the hole with steam winches and wire cable. This plan had to be abandoned, however, because the orifice became too greatly enlarged, a crater apparently having formed.

The second plan adopted was to sink an inclined hole at an angle of about 45 deg., with the idea of intersecting the burning well at about 300 or 400 ft. from the surface, when a charge of nitro-glycerin was to have been inserted and discharged, with the idea of choking off the flow of oil. On July 17 the well tore itself loose, forming an immense crater. The solid column of flame began to weaken, and a part of the oil fell to the ground, burning in the "cienaga," or marshy land, on the edge of which the well was situated, forming a lake of fire about 300 ft. wide round the well. On July 25 the crater was more than 150 ft. in diameter, the great area of the opening making it necessary to abandon the project of drilling angle wells.

It was then decided to install centrifugal pumps and to pump sand and gravel into the crater to choke the well. This was carried into effect, and on the night

of Aug. 30, after having burned for 57 days, the fire was extinguished, the gushing in the meantime having become intermittent, at times ceasing almost entirely. It was during one of these periods when the pressure was weakest that the fire was extinguished by the continued caving, aided by the sand and gravel pumped into the crater.

On Oct. 1 the flow from the well was estimated to be about 3,000,000 bbl. of water and 15,000 bbl. of oil daily.

ATTEMPTS TO SAVE THE OIL

The Mexican government sent engineers and an entire battalion of 450 sappers to aid in extinguishing the fire and in saving the oil from the well. The battalion

THE BURNING OIL WELL NEAR DOS BOCAS, MEXICO. THE COLUMNS OF FLAME AND SMOKE ROSE TO A HEIGHT OF 1500 FEET

Three weeks after the fire was out the diameter of the crater was 400 ft. Soundings taken 30 ft. from the sides showed a depth in places of 200 ft. Approximately two acres of earth dropped into the crater at one time. The immense flow of water and oil had forced an outlet into the Tamiahua lagoon, and for miles the surface of the water was covered with oil

of sappers remained at San Diego until Nov. 1, when the continued caving of the crater made it necessary to abandon entirely the plans for saving the oil.

The work of building dikes, sluices and earthen storage reservoirs for saving the oil has been surrounded with great difficulties. Fully one-third of the working time was lost due to the noxious gases

from the crater, the fumes making it impossible for the men to work when the wind was from the west. Excessive heat and mosquitoes added further to the difficulties.

The plans for saving the oil were based upon a careful study of the conditions and an estimate of the probable future behavior of the well. On Sept. 12 it was believed that the caving of the sides of the crater and the flow of water, mud and oil might soon be limited or interrupted by natural causes. The record kept during the sinking of the well shows that at 330 ft. hard rock was struck, and no change in record until 422 ft. was reached, indicating a stratum of rock approximately 100 ft. thick. It was believed that the opening through this stratum must be restricted, because the hard rock would resist erosion better than the looser *choy*, or marl, which was carried out of the well in immense volumes by the water. The solids in the mud ejected from the crater amounted to 17.06 per cent. by weight and 6.81 per cent. by volume.

quenching the flames by rendering the flow so intermittent that the oil on the surface had time to burn itself out before a fresh outburst from below could supply additional fuel; but it failed to control the flow permanently. No plan could take sufficiently into account the enormous forces which developed as the caving of the crater progressed.

PLANS FOR STORAGE

The ingenious plan adopted for saving the oil was based upon the reasonable assumption that the 100 ft. of rock, 330 ft. down, would hold the bore to fairly narrow dimensions, and that the caving of the sides of the crater would, therefore, cease. Hundreds of men and many mule teams with scrapers were set to work to throw up a dike inclosing the opening. A flume with a suitable gate was to be built at the surface to draw off the water and mud into the lagoon while the layer of oil, which was expected to separate in the crater itself, was to be drawn off at a higher elevation into stor-

BEYOND HOPE OF CONTROL

The following extract from a letter from one of the engineers on the ground dated Oct. 12, suggests the helplessness of engineering science when confronted with the extraordinary forces manifested in this remarkable gusher:

"Every morning we wake up wondering what new phase of the situation will force the adoption of changes in our plans, or the inauguration of new measures. The bigger the hole bores out the more water comes; and the more water comes, the greater the quantity of solids thrown up. I saw the well belch yesterday up to a height of 30 ft. beyond the normal surface and over an area as big as the patio of the office building. If the water continues to come under the same pressure as formerly, and such seems to be the case, more water is but a question of the enlargement of the orifice through which it reaches the surface, and this orifice is periodically enlarging itself by washing away and caving in the walls of the well. As fast as they cave in the water conveys the cavings to the *ciénega* and the lake.

BUILDING DIKES FOR STORAGE OF OIL

BATTALION OF SAPPERS SENT BY THE MEXICAN GOVERNMENT

If the opening in the hard stratum at 330 ft. remained fairly restricted the width of the crater at the surface would be limited by a definite angle. The caving banks contained a certain amount of gravel in addition to the loose material floated out into the lagoon. It was believed that this gravel might settle and choke the well at the narrow orifice long enough for the finer *choy* to settle and form a temporary plug in the well.

Another hard stratum of rock was encountered by the drill at 1128 ft., and it was believed that much of the enormous volume of solids carried out of the well was derived from the soft strata between this and the hard rock nearer the surface. The second plan for plugging the well contemplated sinking an inclined well to the bore in the upper hard stratum and then choking the opening by shattering the rock with explosives. The third plan for controlling the flow involved the introduction of thousands of tons of gravel into the conical crater by means of powerful centrifugal pumps. This plan was successful to the extent that it extinguished the fire, or at least aided in

age reservoirs. But the walls of the well continued to cave and the flow to increase. Apparently the hard stratum at 330 ft. had been undermined and was breaking up. Finally the fumes from the well became so serious and the crater encroached upon the earthwork to such an extent that the well had to be abandoned.

Some idea of the enormous forces at work in this remarkable well may be gained from the estimates of the flow. While the daily flow on Oct. 1 was approximately 3,000,000 bbl. of water and 15,000 bbl. of oil, on Nov. 1, when the well was finally abandoned, the total volume had risen to 14,000,000 bbl., the oil being thoroughly emulsified with water and mud. On Sept. 12 the oil ejected from the well covered an area of about 20 sq.m. on lake Tamiahua. On Oct. 12, the approximate volumes of solid matter carried from the well into the San Geronimo river and into lake Tamiahua was from 30,000 to 50,000 cu.m. At that date a captain of a steamer plying these waters reported that the wheel of his vessel stirred up *choy*, mud and asphalt four miles off the mouth of Dos Bocas.

"Where this condition will stop no human being can predict, but if the pressure continues to come as the orifice opens, cavings will continue indefinitely. The force that is moving the immense volume of water outward must be expended before this well will permanently choke itself.

"The oil flow since the cave of last night has been almost *nil*, but it is entirely possible that it is so heavy with *choy* emulsion that instead of floating it sinks, and passes outward in the lower levels of the flowing stream, in some places 6 ft. deep, and running at the rate of 4 ft. per second.

"After every heavy caving the oil comes in heavy emulsion and gradually clears itself to pure oil as the well purges away the cavings. The periods when pure oil has been flowing have been very few and of short duration during the past 10 days. While I believed that the cavings would become greater as the arch in the perimeter of the well flattened, I never believed that they could become as rapid as they have in the past week or so, and the water flow is carrying away the cavings as rapidly as they come in."

The Rare Metals, VI—Titanium

By CHARLES BASKERVILLE*

Titanium is almost invariably present in igneous rocks and in the sedimentary material derived from them. It occurs in soils and clays, and 784 out of 800 igneous rocks analyzed in the laboratory of the United States Geological Survey contained titanium. The titaniferous minerals, which seldom occur in considerable quantity in any one locality, are named in the accompanying table. However, extensive deposits of titanium ores are known.

TITANIUM MINERALS.

	Titanium Dioxide Content.
Rutile, titanium dioxide, ...	90-100%
Balsontite, a variety of rutile.	70%
Iserte, a variety of rutile.	90-100%
Dicksbergite, a variety of rutile.	90-100%
Brookite, titanium dioxide.	90-100%
Octahedrite, titanium dioxide.	90-100%
Ilmenite, iron titanium oxide.	3-59%
Titanite, calcium titanium silicate.	35-45%
Pseudobrookite, a ferric titanate.	14-35%
Perovskite, calcium titanate.	59%
Geikielite, magnesium titanite.	68%
Senaite, composition uncertain.	57%
Zirkelite, a titanio thorio-zirconate of iron and lime.	15%
Knopite, a titanate of calcium, iron and cerium.	54-59%
Derbyllite, a doubtful iron, antimony and titanium oxide.	34.5%
Lewisite, a titanio-antimonate of iron.	11-12%
Manzellite, a titanio-antimonate of lead and calcium.	7-8%
Neptunite, a titanio-silicate of iron and alkali metals.	17-18%
Haimite, a silicate of sodium, calcium, titanium, etc.	
Polymignite, a niobate and titanate of cerium, iron, etc.	19%
Aeschynite, a niobate and titanate of the cerium metals.	21%
Pyrochlore, chiefly a niobate of the cerium metals, etc.	5-14%
Dysanallyte, a titanio-niobate of calcium and iron.	40-60%
Rinkite, a complex silicate of titanium, calcium, etc.	13%
Mosandrite, a complex silicate of cerium, etc.	5-10%
Johnstrupite, a complex silicate of cerium, calcium, etc.	7-8%
Astrophyllite, an orthosilicate of titanium, etc.	7-14%
Lamprophyllite, composition doubtful Kellhaute, a titanio-silicate of calcium, yttrium metals, etc.	26-37%
Schorlonite, analogous to garnet.	12-22%
Guarinite, calcium titanium silicate.	34%
Tschefskinite, uncertain composition.	16-21%
Euxenite, a niobate and titanate of yttrium, uranium, etc.	20-35%
Polyrase, a niobate and titanate of yttrium, etc.	25-36%

The important titanium minerals are rutile, brookite, octahedrite, perovskite, ilmenite and titanite.

USES OF TITANIUM

The addition of titanium in minute amounts to iron and steel increases the tensile strength greatly; ferric titanium is useful in cases where a metal of considerable density and hardness is required, as in the manufacture of car wheels. Titanium steel is employed for cutting tools. The addition of titanium to steel containing 0.8 to 1.2 per cent. of carbon scarcely increases the hardness, but greatly raises the elasticity. On account of the beautiful light effect it produces during combustion, titanium has been used in pyrotechnics. It is also used in

the manufacture of filaments for incandescent electric lamps, and for incandescent media for gas lights. With the development of the electric furnace treatment there will be a market for titaniferous iron ores.

Titanium dioxide has been used for some time in the manufacture of artificial teeth, and in the preparation of a glaze for earthenware; more recently it has been employed as a mordant for wool and cotton. Titanium mordant yields bright and fast colors intermediate in shade between the colors produced by chromium and aluminum. Titanium dioxide has also been utilized in the manufacture of a protective paint for iron and steel. Titanium sesquioxide and its salts are employed as reducing agents, sodium titanous sulphate and titanous chloride having been found most useful.

Titanium tannate may be utilized as a self-color for fibers or the material may be further dyed with basic coloring matters. Titanium oxalate, potassium titanium oxalate, "tanno-potassium titanium oxalate," and the double tartrates and lactates of titanium with alkali metals are used in leather dyeing. Titanium ferrocyanide is employed as a substitute for the poisonous Schweinfurth green and other arsenical pigments.

RUTILE

Rutile, or nigrine, occurs in reddish brown to nearly black prismatic crystals, which are often acicular in form and as such included in other minerals. It is found occasionally massive, especially when black and ferri-ferrous. Rutile occurs as a pyrogenic mineral in eruptive rocks, but is more common to gneiss, mica schist, and the phyllites. It also is found as a secondary mineral derived from ilmenite and titanite. Rutile is a brittle mineral, having a hardness of 6-6.5, and a specific gravity of 4.18-4.25. Its luster is adamantine to almost metallic, and the cleavage is prismatic and pyramidal. The streak is pale brown. It is found in Maine, New Hampshire, Massachusetts, Connecticut, New York, Pennsylvania, New Jersey, North Carolina, Georgia, Arkansas, Colorado, and in the Black Hills, Dakota. The most prominent of these localities are Lincoln county, Ga., Habersham county, Ga., Warwick, N. Y., Warren, Me., and Magnet Cove, Arkansas.

Rutile is infusible before the blowpipe. It dissolves very slowly in salt of phosphorus in the oxidizing flame to a yellowish bead, which assumes a violet color in the reducing flame on cooling. Ferri-ferrous varieties give a brownish yellow or red bead in the reducing flame, so that a violet color is only obtained after treating the bead with metallic tin on charcoal. It is insoluble in acids. However, it dissolves by fusion with an alkaline carbonate; the solution, after the addition of an excess of acid and tin-foil, yields a violet color on boiling.

Rutile is of a more decided red color and of lower specific gravity than cassiterite; and may readily be discriminated from garnet, pyroxene, vesuvianite, and tourmaline by its luster, weight and infusibility.

BROOKITE

Brookite is found in thin, tabular, brown crystals, or in black opaque crystals, habit varied, in the Ozark Mountains, Ark., North Carolina, Ulster County, N. Y., and at Paris, Me. Its hardness is 5.5-6, and the specific gravity is 3.87-4.07. The luster is submetallic to adamantine, and the streak may be uncolored, gray, or yellow. Arkansite, as the variety from Magnet Cove, Ozark Mountains, Ark., is called, occurs in stout crystals, brown to black in color, associated with calcite, black garnet, schorlonite, and rutile, to which it alters on the surface by paramorphism. At Ellenville, N. Y., brookite is found on quartz with galena.

The pyrogenic deportment of brookite is the same as rutile.

OCTAHEDRITE

This mineral occurs in light brown, deep blue and black pyramidal crystals at Smithfield, R. I., and Brimbleton, N. C. At the latter locality, it is found in transparent tabular crystals. The luster of octahedrite is metallic to adamantine, and the fracture is subconchoidal. It is brittle, and the hardness is 5.5-6 and the specific gravity is 3.82-3.95. The streak is white. Octahedrite is never primary, but is formed by the alteration of other titanium minerals.

Octahedrite behaves like rutile before the blowpipe. Its specific gravity increases to about that of rutile on heating.

PEROVSKITE

Perovskite, or perovskite, occurs in pale yellow to grayish-black cubic crystals and in reniform masses. It has been noted as a rock constituent in the form of very small octahedral crystals. It is found in Elliott county, Ky., and at Syracuse, N. Y. The hardness is 5.5, and the specific gravity is 4.01-4.04. The luster is adamantine, and the streak is colorless or grayish. It is transparent to opaque.

Perovskite is infusible before the blowpipe. With salt of phosphorus it dissolves readily in the oxidizing flame to a greenish bead while hot, but which becomes colorless on cooling; in the reducing flame the bead assumes a violet blue color on cooling. It is decomposed by sulphuric acid, but is insoluble in hydrochloric acid.

ILMENITE

Ilmenite, menaccanite, or titanio iron-ore, is an iron-black mineral, which is found usually massive, in thin plates, in embedded grains, or loose as sand. It occurs in Orange county, N. Y., Massachusetts, Litchfield, Conn., Troy, Vt., and

*Professor of chemistry, College of the City of New York.

in California. Extensive beds of ilmenite occur in Quebec, Canada. Its hardness is 5-6, the specific gravity is 4.5-5, and the luster is submetallic. The fracture is conchoidal. The streak is black to brownish red. Ilmenite slightly influences the magnetic needle.

Ilmenite is infusible in the oxidizing flame, but is rounded on the edges in the reducing flame. It reacts for iron with borax and salt of phosphorus in the oxidizing flame, and yields a brownish-red bead in the reducing flame with the latter salt; this changes to a violet-red color when treated with tin on charcoal. The powdered mineral is soluble in hydrochloric acid to a yellow solution, which assumes a blue or violet color when boiled with tin. It is decomposed on fusion with sodium or potassium disulphates.

Ilmenite is distinguished from magnetite and hematite by the titanium reactions described above. It is used in the preparation of a lining for puddling furnaces, but is not very desirable as an iron ore on account of the difficulty in reducing it.

TITANITE

Titanite occurs in brown, gray, yellow, green, rose-red, and black, wedge-shaped or tabular monoclinic crystals. It is sometimes found massive, and rarely lamellar. The luster is adamantine to resinous, and the streak is white. The hardness is 5-5.5, and the specific gravity is 3.4-3.56. It occurs in Maine, Massachusetts, Trumbull, Conn., Lake George, N. Y., Franklin Furnace, N. J., Bucks county, Penn., and in Iredell, Buncombe, and Alexander counties, N. C. At Green River, N. C., large crystals of sphene, or titanite, occur completely or partially altered into xanthitane. Good gem stones of titanite have been found at Brewsters, N. Y., Bridgewater, Penn., and Magnet Cove, Arkansas.

Before the blowpipe, some varieties change color, becoming yellow, and fuse to a dark glass with intumescence. Titanite gives a violet bead with salt of phosphorus in the reducing flame. The borax bead is clear yellow-green. It is, partly soluble in hydrochloric acid, and if the solution is concentrated after the addition of tin, it assumes a violet color. It is completely soluble in sulphuric acid.

Aluminum Coins in France

M. Caillaux, French Minister of Finance, is shortly to place before the Chamber a bill in which he proposes to replace the small old-time copper coins by new coins of aluminum. He has had some aluminum coins struck at the mint, which have met with approval. The new 5- and 10-centime coins are to be of exactly the same size as the copper coins now being used, the only difference being in weight.

Zinc Mining in New Jersey *

By HENRY B. KUMMEL†

The zinc mines at Franklin Furnace and Ogdensburg, both controlled by the New Jersey Zinc Company, are the only mines of this character in the State, and during 1907, as for a number of years past, only the Franklin deposit was worked, the mines at Ogdensburg having been indefinitely closed down a number of years ago. The richness of this ore, the great size of the orebody and the large rewards awaiting the discoverer of additional deposits, have led, first and last, to the expenditure of large sums of money in prospecting the adjoining territory. The zinc deposits occur only in the white crystalline limestone, the limits of which are accurately known. It is safe to say that every foot of this belt has been carefully examined on the surface without revealing any evidence of additional deposits. In addition to this thousands of dollars have been spent in diamond drilling on all sides of the known deposits, but without avail. It is unquestionably true that in some instances the drilling ceased before the ground had been thoroughly tested, i.e., before the holes reached the bottom of the limestone, but since the holes were in some instances at least 1300 or 1400 ft. deep, it was demonstrated that no zinc deposits occurred within easy reach of the surface where they were drilled. The absence of any surface indications of zinc ore, and the utter failure of all the drilling to reveal a deposit other than those which have been mined for many years, afford at least very strong presumptive evidence that no other deposits exist. And, while there is always the possibility that zinc ore similar in character to the Franklin ore may occur somewhere within the limits of the white limestone, yet the probabilities of finding it by a few diamond-drill holes put down at random are so remote that any exploration of that character must be regarded as a highly speculative venture in which the chances are against success. It seems advisable to make these emphatic statements in view of the large sums of money recently obtained by a mining company on the alleged occurrence of valuable zinc deposits on property adjacent to the established mines.

The New Jersey Zinc Company reports its production in 1907 as 329,205 tons of ore, a little less than half of this having been taken from the open cut at the south end. This is a decrease of 32,120 tons as compared with 1906. The Palmer shaft, started in 1906, enters the blue limestone of the footwall, near the mill, at an angle of 47½ deg. At the close of the year, it had been sunk 580 ft. and was in the gneiss underlying the white limestone. Since the blue limestone and associated

sedimentary beds dip to the westward at an angle of about 50 deg., the shaft crosses the bedding planes nearly at right angles. The gneiss was reached 230 ft. from the collar of the shaft, and from that point to 580 ft. and beyond the rock was gneiss, the foliation and fracture planes of which dip eastward at an angle of 70 degrees. At 402 ft. from the collar of the shaft, a small vein of zinc blende, which dipped about 50 deg. to the west, was struck. It measured from 1 to 3 in. in width and was associated with quartz and fluorite.

[The emphatic remarks of Doctor Kummel are highly praiseworthy and ought to do much to prevent the inception of fraudulent and visionary schemes such as have frequently been dangled before unwary investors in the past. This is an exemplification of one of the highest functions of a State geologist.—EDITOR.]

Pulverized Shale for Prevention of Coal Dust Explosions

Experiments at Lieven, France, in the laboratory maintained by the Comité Central Des Houillères de France, recently demonstrated the value of a new explosive, "grisoutine couche," to overcome the danger of secondary explosions of coal dust, and also that coal dust mixed in the proportion of six to four with pulverized shale cannot be exploded. A gallery constructed of armored concrete fitted with protected glass observation holes was used to show the progress of explosions. Nothing has yet been said about the industrial value of the discoveries, as some experiments have yet to be made in order to discover to what extent local applications of shale dust will prevent explosion.

The laboratory is making experiments with apparatus of all kinds intended for preventing disasters in the mines, or for making it possible to inaugurate intelligent relief work very soon after any disaster has occurred. Among the specialties of the laboratory is a department for testing and mending anemometers which are used for recording the draught caused in different parts of the mines by the ventilating fans.

In Victoria, Australia, the State mining law requires 70 cu.ft. per minute of air to be supplied to each miner working in the mine and that the air in the mine shall not contain less than 20 per cent. oxygen, nor more than 0.3 per cent. carbon dioxide. The Western Australian Mining Commission in 1905 considered that not more than 0.15 per cent. carbon dioxide should be allowed and that it should not be difficult for mines to meet that demand. Dr. Angus Smith, of the English Mining Commission, recommends 0.24 per cent. carbon dioxide as the limit of impunity in mine air.

Views Respecting Coal Mine Explosions

Engineers Discuss Statements of Mr. Haas, Mr. Page and JOURNAL Editorial of Dec. 12, Relative to Colliery Accidents, Cause and Prevention

A SYMPOSIUM OF OPINIONS

The following letters, including the longer article by Mr. Stow, have been written in reply to recent arguments advanced to explain the chief causes of coal-mine explosions. The authors differ radically in some of their views; however, it is only through the fearless expression of such personal opinions that the maximum benefit will result.

Blown-out Shots and Miners' Negligence Cause Many Explosions

By CARL SCHOLZ*

I have read with interest your editorial in the issue of Dec. 12, on "Colliery Accidents." If you will compare the accidents which existed prior to the adoption of the mine-run basis, or when coal was mined in this country very much on the same basis as it is now produced in England, Belgium, Germany and France, which countries are held up as examples, you will note that our accident ratio then was very much lower than it is now. While Mr. Mitchell stated that 60 per cent. of the fatal accidents are due to rock falls, it is well known that increased rock falls are due to excessive use of explosives and shooting from the solid.

The Mine Workers' organization has been forcing the majority of the mining fields to use the mine-run basis, and in some sections this has resulted in the adoption of mining machines to prevent excessive waste. Even if not a single explosion could be prevented, but I think they can, if we could reduce the accidents from rock falls to one-half by cutting the coal before blasting it, the greatest possible step in the direction of saving lives and preserving the coal will have been made. There might have been some good reason to adopt the mine-run basis, but once it is proved to be detrimental, it seems to me that the mine workers should be willing to change their attitude.

In talking with a number of officials, I find that, individually, they are favoring the readoption of pick mining, and it seems to me this will place a premium on the good miner and force out of the mines such men as are not qualified to be miners

and are a menace to the safety of their fellow employees.

Electric shot-firing is a great safeguard and shot-firers reduce the risk to a smaller number of men, although as long as the coal was properly mined and undercut, there was no necessity for this course. Blown-out shots generally result where coal is not properly mined, or where it is shot from the solid; there is no excuse for blown-out shots where mining machines are used and the coal is properly snubbed. Solid-shooting is responsible for an increase in the cost of production and requires the consumer of domestic coal to pay the greater part of the expense. In coking-coal districts, this feature is not of as much importance as in territories where domestic coals are produced and where the small coals command lower prices, as is the case in Illinois and Indiana.

Why should the operators be compelled to go to the expense of inspection and installation of expensive apparatus, when the miners, merely as the result of a fad, continuously and daily force the assumption of risk of life and property?

Facts Disproving Recent Statements Relative to Mine Fatalities

By JOSEPH VIRGIN*

In reference to the article of Wm. N. Page in your issue of Dec. 5, Major Page says, "After a careful study of the Paper of Mr. Haas and the Report of Foreign Experts, etc.," two facts seem to be established: 1. That dust as dust is not explosive. 2. It is physically impossible to moisten dust to the point of safety in high velocity currents. After a careful study of Mr. Page's paper, and the other papers mentioned by that gentleman, as well as your editorial of Dec. 5, six facts seem to be established: First, dust in a quiescent state is not explosive. Second, dust is not quiescent in a high velocity. Neither is it quiet after a slight concussion, such as accompanies falls of roof, or the concussion from shots or moving trains. Third, Mr. Haas is an advocate of fine spray moistening with water or steam, or any method that is convenient, and is practicing it. Fourth, Messrs. Watteyne and Meissner concur in this. Fifth, the statement that 60 per cent of all mining fatalities are due to roof

falls, is not borne out by figures, especially West Virginia, and more especially in that same State for the years ending June 30, 1905, 1906, 1907, and 1908. Sixth, moisture in the air does not seem to be a particular cause of the fatalities in West Virginia or Pennsylvania.

As to the first consideration, fine dust in a quiet state is not explosive because it is *en masse*. You cannot get a flame around it, neither is there enough oxygen around it to make a flame with it. But upon the least provocation it is stirred up and is surrounded by its own atmosphere of air and Professor Abel says it will ignite at 700 deg. F. Such being the case, it is immaterial whether it detonates, bursts into flame or explodes; the result is the same, the men are killed.

Concerning the second fact, dust won't stay quiet. You may shut down your fans and let all the dust settle, but just as soon as you start them up again the dust begins to move; furthermore, the air acts on the rocks, and falls occur, forcing the very finest and the most dangerous dust out on any flame that may be near; the dust is also disturbed by any movement of cars, and the high velocity of rope trips or motor trains causing the gauze of safety lamps to be clogged, making them pass the flame at a much less velocity, thereby greatly intensifying the danger.

Third, Mr. Haas not only advocates steam and fine sprays to moisten dust in high velocities, but is contemplating a long steam line to warm the winter air to assist it in getting the moisture from the sprays or steam more quickly. However, if you clean up the dust and do not allow it to accumulate, you will not have any dust to water, and it will only be necessary to keep the fine coal damp so that it can be removed before it becomes dust.

Fourth, at the meeting of the West Virginia Mining Association, Doctor Holmes and the foreign experts gave us strong advice on the good results to be obtained from watering, and the results of the investigation tests in Europe.

Fifth, let us take the West Virginia reports for the years 1897-1907, inclusive; the following results are shown:

Total lives lost	1699
Falls of roof, coal, etc.	928.54 per cent. was due to falls of roof, etc.
During 1905, lives lost	176
Due to falls of roof, etc.	105
During 1906, lives lost	250
Due to falls of roof, etc.	99
During 1907, lives lost	324
Due to falls of roof, etc.	139
	750 343

Take the year ending June 30, 1905, we find 50 lives were lost in all kinds of

*Mining engineer, Chicago, Ill.

*Mine superintendent, Plymouth, West Va.

explosions. Then for the year ending June 30, 1906, we find 113 lives lost from the same cause. In the year ending June 30, 1907, there were 147 lives lost from mine explosions.

FATALITIES IN WEST VIRGINIA

	Total Lives Lost.	By Explosions of All Forms.	Due to All Kinds of Explosions.
1905....	176	50	28 per cent.
1906....	250	113	45 per cent.
1907....	324	117	45 per cent.
1908....	will probably show 60 per cent.		

As Mr. Page's open letter was directed to the mine managers of West Virginia, Mr. Page being an operator in this State, his figures are somewhat misleading. Mr. Paul, in his report for 1907, to the Governor of West Virginia, makes the following statement: "For the third time in the history of the State, the number killed by explosions exceeds that of persons killed by falls of roof."

The elaborate report of the Pennsylvania mining department for 1904, and covering the bituminous mines of the State, shows that the loss of life due to falls of roof, was 37.98 per cent. Again referring to the last mentioned report, for the year, 1904, I submit a few figures to show that moisture as appearing in the summer months is no more dangerous, from a standpoint of lives lost, than when occurring in the colder months.

FATALITIES IN PENNSYLVANIA

Month.	Killed by Falls of Roof and Slate	
Dec....	20	{ Cold months, least saturation.
Jan....	14	
Feb....	13	
March...	14	{ Slightly warmer months, a little more moisture.
April....	20	
May....	23	
June....	13	{ Extremely warm months, highly saturated.
July....	51	
August...	21	
Sept....	12	{ Normal temperature, average humidity.
Oct....	19	
Nov....	17	

In the years 1905, 1906, 1907, ending June 30, I produce the following from the West Virginia Mine Reports:

MEN KILLED BY FALLS OF ROOF FOR THE THREE YEARS.

Month.	Total Fatalities.	
Dec....	32	88 Winter months.
Jan....	26	
Feb....	30	
March...	17	64 Spring months.
April....	23	
May....	28	
June....	17	64 Summer months, most moisture.
July....	26	
Aug....	22	
Sept....	24	64 Fall months, normal temperature.
Oct....	21	
Nov....	19	

All the figures gleaned from the bituminous mine reports of Pennsylvania

and those of West Virginia, prove that as far as the mines of those two States are concerned, that the months in the year containing the most moisture are not particularly dangerous; in fact West Virginia seems to be safer in the hot months.

The foregoing figures also disprove the statements that 5 per cent. of our accidents are due to dust explosions, and 66 per cent. to falls of roof. Mr. Page probably means all kinds of mines, not coal mines alone. In conclusion, I desire to approve of the policy of keeping dust damp and using large currents of air. West Virginia allows only 60 men in each split, and it follows, therefore, that in a mine of 300 men, there must be 5 splits, or the law is violated, consequently, it appears that Mr. Page's advice to split, is ancient.

Timely Suggestions as to Shot-firing in Coal Mines

By R. J. J.*

I have read with great interest your editorial of Dec. 12, on "Colliery Accidents," also the description of the events connected with the Marianna explosion. I am glad to note your reference to the action of the National Institute of Mine Inspectors, at the Pittsburg meeting of the Mining Congress. The inspectors, as a rule, are underpaid, if one considers the character of their duties, and should be encouraged in their work rather than censured. The press bulletins issued during the past year may have been necessary in order to influence public sentiment so that appropriations for the work of the Federal Technologic Division would be forthcoming; however, I believe that they have tended to throw an air of mystery around mine explosions in the minds of the general public. We all know that mine gas and air will explode; there is no use to erect expensive apparatus to demonstrate this fact, but we do not know just what explosives at present on the market are safe, and the investigation of such substances, by the Survey authorities, is to be commended.

THE EMPLOYMENT OF SHOT-FIRERS IS ADVISABLE

As to the employment of shot-firers, I believe that you have not grasped the full significance of Mr. Mitchell's remarks. I have not read his address, and can only gain an idea of what he said as you refer to it. He doubtless refers to the Illinois Shot-firer's Law. This was necessary, as the inspectors found that explosions were becoming more frequent. They reasoned that it would be better to employ shot-firers to shoot the shots than to allow the miners to shoot their own shots. These

shot-firers would shoot the holes when they were alone in the mine, after all the miners had left the workings. Since the adoption of this plan, there have been numerous small explosions, many of them undoubtedly due to powder poorly placed in the holes, and a number of the shot-firers have been killed. Had these explosions taken place under the old rule of allowing every miner to shoot his own shots, when the entire force was in the mine, the loss of life would have been in many cases, I venture to assert, at least as great as that in the Marianna explosion.

As it was, only the shot-firers, of which there are rarely more than 6 or 8 in number, and usually but 2, were lost. It seems to me that the Illinois law, so far as it has been enforced, is a good one, and should be extended to other States. But, it has its imperfections. Usually, active men are required for the work of shot-firing, as the men must be able to quickly traverse the entire mine workings in order to shoot all the shots in a short space of time. For this reason the older and more experienced miners will not do the work, and it is often relegated to younger and less experienced men; often, indeed, to drivers, who are proverbially prone to take chances. Moreover in some cases, the practice has been to allow the shot-firers a shift's wages for shooting a certain amount of shots, and, as a consequence they have hurried through the work, sometimes taking reckless chances which resulted to their sorrow. This is not general, but such cases have occurred. However, this is the fault of the men, not of the system, and where it is wisely carried out, it will prove in the end a life-saving innovation.

PROBABLE CAUSES OF EXPLOSIONS

One thing that has been a source of wonder to many, is why we are of late years, having more and more explosions, where we never had any before, and where the method of mining is the same as it has been for 30 to 40 years past, and the men are experienced in the system used. I refer more especially to solid-shooting mines. Is it because the general run of miners are not now as skilled as formerly, or is it because the powder manufacturers now use different ingredients in their powder, than they did formerly? In support of the first question, I have recently heard of instances where the shot-firer found cartridges placed for him to shoot, which were longer than the hole was deep. As to the second question, the use of an ingredient with greater flame-producing powers than that formerly employed might cause explosions.

Another factor which I think is neglected, is the element of time. Formerly, the men fired their shots under the ten-hour day custom, anywhere from 4:30 to 6 p.m. Now, under the eight-hour day, the shots are fired nearly all in the

*Mining engineer, Baltimore, Md.

space of time varying from 15 to 30 min., or from 3 to 3:30 or from 4 to 4:15 or 4:30 p.m. Many more men are now employed to produce a given output than was formerly the case, and more powder is used per ton of coal than formerly; all this powder is exploded in from 15 to 30 min., where shot-firers are not employed, and occasionally when they are, although the time formerly required for such work was from two to three hours. The liberation of such a great volume of gas from powder explosions in such a short space of time, may be a contributory cause.

As to the Marianna explosion, you do not say so, but I presume that there was indiscriminate shooting, that is, the men fired when they wished, at any time during the shift, and not at the close of the shift, as they should. Perhaps this was the case also at Monongah.

Now from your sketch I note that there was no wide work under way at the Marianna mine at the time of the explosion, all the men being engaged in driving headings. If such was the case, and the coal was thick, say 8 to 10 ft. in thickness, and the narrow entries were passing a large current of air at a high velocity, the only factors necessary for trouble was the presence of some gas, a coal making a fine dust, and some entryman shooting a gripping shot. The large volume of air at a high velocity would accentuate the explosive force of the powder on the air. If some men were working ahead of the air, and the entryman and crosscutman fired at the same time, an explosion might easily result. I have known of such instances. Incidentally, I believe that no man should be allowed to work "ahead of the air;" the distance between the crosscuts between entries should be established and rigidly adhered to, and the mine foreman or inspector should be allowed no option in the matter. Brattice work is all right, but a good crosscut is better.

As hearing on the question of intelligence of miners and frequency of accidents, I would refer you to the Maryland coalfields, where, in 1907, the death rate per 1000 employees was 0.64. Some 6201 miners are employed and over 1,000,000 tons mined for each fatal accident. More-over most of the coal worked is quite thick, and a poor roof covers the coal, so that the miner must use great care in his work. It is also true that no gas is encountered in the mines. The miners are nearly all Americans of a high order of intelligence. The inspector and companies in most cases work in harmony, and there is good discipline in the mines. The above is presented for your consideration, as it may lead to some changes in the present system of shot firing in use in portions of Pennsylvania. The attention of those who compare the death rate in American mines with those in European countries, is directed to Inspector Murphy's reports for Allegheny and Garrett counties, Maryland, for the past three years.

High Currents in Mine Ventilation

By W. C.*

It is most disgusting to read and hear the flow of "rot" that is being spread over the land, as to mine accidents and their prevention. The whole question resolves itself into one of candor or hypocrisy. The men who know most about the subject are thrust into the background, and if they say anything it is drowned by bel-lowlings of mediocrity.

Accidents don't happen in pits where people are looking for them, but generally in those workings where the best management is said to prevail. Throughout the entire world the highly gaseous mines are well looked after. The new craze that pits are getting too much wind, is simply an endeavor to justify those who have too little, and who wish to continue to work dangerous mines with open lights.

It is perfectly true that in the case of ignition a vigorous current of air lends force to the blast; it is also true that the air can be so split and directed that its velocity will be kept down to a safe limit, in working places. No one will deny that a vigorous air current will remove the finest particles of dust; but they will be deposited in wide places in returns, where they constitute far less of a menace to safety than they do while they remain in the main haulways and the chambers that are being worked.

Dust as a Factor in Mine Explosions

By C. S.†

I note in your issue of Dec. 5, the letter written by William N. Page, on "Dust as a Factor in Mine Explosions," and also note your editorial comment on the Marianna explosion. I concur with you in your analysis of Mr. Page's letter, especially that part referring to the increased rock falls due to the introduction of moisture, having given this subject close attention for two years.

In the first place the accidents due to rock falls occur at the face of the rooms and are due either to careless timbering, or excessive use of explosives; the effect of the moisture, where it is noticed in mines, occurs on the intake entries. I have found, however, that where the air is fully saturated constantly, the rock falls in the summer are not nearly so great during the sweaty season; the change from wet to dry causes disintegration of rocks and decaying of wood, whereas if constantly submerged or kept dry, this material is not affected by the action of the atmosphere. What applies to rock out-

side, undoubtedly applies in the mine as well, and it is noted that such places in the mines as have seepages throughout the year usually have a better roof.

The increase in humidity in the winter months in my opinion is by far the most effective measure to prevent, or at least diminish explosions. In machine mines care should be taken to load out the cuttings, and it is possible that one spray should be used in the rooms which are cut just before shooting, in order to remove the flying dust from the air current.

One or two accidents which have occurred recently, have been in mines that produced practically no gas, and it is almost safe to assume that the explosions were due entirely to the dust in the air. In mines where shooting from the solid is practiced, the excessive use of explosives creates much flying dust; as a whole, the mining conditions today are quite different from what they were, say fifteen years ago, when all of the coal was undercut, whereas it is now either shot from the solid or mined by machines. These two modern practices have brought about a change in the mining conditions, the importance of which is perhaps not appreciated, because the changes were made gradually.

The Control of Coal Mine Explosions

By HARVEY J. NELMS*

In your issue of Dec. 5, you print an article by Wm. Page, of West Virginia, on "Dust as a Factor in Mine Explosions." In my experience with coal mining, as a mining engineer, I cannot believe that the fatal accidents resulting from falls of slate are caused by the dis^{c} integration of the slate by water. The faults in coal seams, such as clay partings, etc., generally denote a wet entry, and I am sure superintendents of coal mines will agree with me in saying that 75 per cent. of the fatal accidents due to falls of slate, etc., may be explained by the old text, "death due to error of judgment on the part of the injured in setting post wrong." As to splitting air currents, etc., I cannot regard this plan as being a possible preventive of the so-called dust explosions.

DUST ONLY IGNITED BY FIREDAMP

In a mine which generates firedamp in dangerous quantities, I am sure the smaller factor of the two to guard against is dust. We know what gas will do if allowed to reach a proper mixture, while dust is only dangerous when the firedamp sets it off. I cannot believe that a dust explosion will take place when started by anything but a firedamp explosion.

Everybody working in coal mines knows

*Mining engineer, Pennsylvania.

†Mine manager, Chicago, Ill.

*Mining engineer, Bentleyville, Penn.

of entrymen who work from 10 to 100 ft. ahead of the air, although their entry is making gas, and they have 10 or 12 small explosions each day. It is reasonable to believe that once in a while the dust will be so distributed and in proper condition to explode when started by a firedamp explosion. In controlling the ventilation of coal mines, I believe the vapor and so-called wetness or dryness of the air, making up the air currents, should be tested at several places in the mines; by this I mean that if we go on the theory that coal dust will explode when conditions are favorable, then it appears to me that the proper thing to do is to keep the mines from getting in a condition where the dust will be dangerous. In the first place, the miner should not be allowed to load the slack coal made by a mining machine in one car. A room 23 to 27 ft. wide, and 6 ft. deep usually makes just a 2-ton car of slack, the slack filling the car bed full. It often occurs that as soon as the room is cut the miner will load this slack all in one car and by transporting this car to the outside by mule and locomotive power, the dust will impregnate the air as the car passes along the entries.

I believe a better plan would be to load half the slack and then fill the car with loose coal, the latter more or less protecting the air from the slack. It is also advisable that trips should not be hauled at a speed exceeding 10 miles per hour when the mines are very dusty. These are but a few suggestions showing the practical side of controlling coal dust.

I do not altogether believe in Mr. Hass' theory of steam, although steam used for wetting the air currents in coal mines is far better than sprinkling. I feel sure much good will result if we act on the supposition that the only thing to do to prevent coal-dust explosions, is to keep the atmosphere of the mines always in the same condition and not allow any change of atmospheric condition, due to sudden changes of temperature outside, such as the difference between winter, summer, etc. If ventilation is not in any way stopped, and if we keep the absolute amount of water vapor in the air currents always the same, never allowing them to change, then coal dust will not and cannot explode, because as long as these conditions are observed, the chemical reaction necessary for a coal-dust explosion cannot occur.

ALL AIR CURRENTS SHOULD BE REGULARLY TESTED

It is a simple operation to measure the amount of water vapor in a given quantity of air, and it seems to me all coal superintendents would be making a good investment if they would install a small testing station at their mines, so tests could be made three or four times a day. The mine manager could be kept informed of the condition of the atmosphere in the differ-

ent plants under his care, and when the water vapor fell too low, steam could be admitted to the intake air until the mine atmosphere would again come up to the proper standard. As long as the air in the mines is kept at one standard, as regards water vapor, the coal dust will be a minor factor and will not explode. Swift air currents are the best, as they will not deposit their water vapor as fast as slow-moving currents. An aspirator and drying tubes are the only devices necessary to measure the amount of water in a ventilating air current.

PRACTICAL METHODS FOR TESTING THE AIR

One plan is to fill a jar with water, the jar having a stop cork at the bottom; U-shaped drying tubes are also filled with pumice stone soaked with sulphuric acid. The stone is carefully weighed before the experiment, and when the stop cork is turned on and the water is allowed to run out of the jar, this draws an air current through the drying tubes. The volume of air which passes through the apparatus can be found by measuring the water that has run out of the aspirator, and the weight of water in this volume of air can be found by again carefully weighing the pumice stone. The difference in weight between the first and second weighing of the pumice stone gives the weight of water contained in the volume of air which passed through the drying tube.

Another and easier way to test the air is to get some CaCl_2 and place it in a saucer; this attracts the water out of the air, the salt gradually becomes wet and eventually dissolves in the water which it attracts from the air. If taken every morning a person would soon notice any difference in the amount of water contained in the air and could remedy the condition by adding steam if too small, and reducing velocity of air currents, if too much. The standard condition of the vapor in the air should be previously determined by careful investigations, the first and foremost idea being not to allow any change to take place in the condition of the mine air as regards the amount of water contained in the air currents.

We are not going to find a new theory or system for working our coal mines, and consequently, we must make the best use of the knowledge we already possess.

USING A BOOSTER FAN

Mr. Page is wrong in his theory of providing several fans of smaller capacity. If the main fan outside has too much work to do, it can be easily helped by installing an 8- or 10-ft. fan of the Stine type 3000 or 4000 ft. in along the main return airway, providing, of course, that the outside fan works as an exhaust. This booster fan should be operated electrically and belt connected preferably by a three-phase, 440-volt induction motor, if the alternating current can be got. This motor gives

the least amount of trouble on the market, and will operate under most severe conditions for any speed at which it is rated. The speeds usually vary from 150, through nine speeds, to 600 r.p.m.; the motor being belt connected and running the fan at any desired velocity. These fans, when installed, give most excellent satisfaction. The main fan under these conditions works only from the exhaust of the inside fan.

Splitting air currents and the liberal use of overcasts will be most helpful to any mine. It may here be mentioned that the recent coal-mine explosions have only occurred in those mines under the care of the so-called and high-priced expert. The small fellows manage to get along without paying for explosions. It may be well for some of the others to take notice.

Ventilation Is a Question of Quality Rather than Quantity

By P. J. D.*

Mining engineers were no doubt surprised at the proposition advanced by A. B. Fleming of West Virginia, at the recent meeting of the American Mining Congress at Pittsburg. Mr. Fleming then said: "I wonder sometimes if there is such a thing as too much ventilation in the mines?" This question seems to have arisen in Mr. Fleming's mind for the reason that recent mine explosions have occurred in workings that were supposed to be among "the best ventilated in the world."

OUR MINES DO NOT GET TOO MUCH VENTILATION

The speaker, and those who apparently agreed with him according to newspaper reports, appears to have overlooked the fact that the reason especially elaborate ventilation installations exist is that mines so equipped are (in the majority of cases) known to be dangerously gaseous, and therefore liable to be the scene of explosions. It is a strange conclusion, however, that in such cases the cause of explosions lies in the fact that there is too much ventilation. It is much more likely that the ventilation, though perhaps unusually good, was still not good enough, or that gaseous workings were not properly ventilated, even though the mine as a whole was amply supplied with air. Explosions most often occur when the barometer is low, for the reason that the explosive gases are liberated from coal in larger quantities whenever the atmospheric pressure falls, and the greater the volume of air that can be supplied by fans, the more gases are diluted and the smaller the chance of an explosive mixture being formed.

It would seem that Mr. Fleming's doubt

*Mining engineer, New York City.

should have been directed not so much at the existence of too great an amount of ventilation, as at ventilation of a particular kind. Experience and the writings of experts on such matters may be searched in vain for rules against "too much" ventilation. Ventilation is not a question of quantity, but of quality, and that there is room for improvement in ventilation admits of little doubt.

The suggestion made above that explosions are likely to occur in gaseous workings, even though at the same time the rest of the mine is well supplied with fresh air, is borne out not only by general experience, but it is the point especially dwelt upon by the most recent writers on this subject. Speaking of the prevention of coal-mine explosions, W. B. Williams, in the *ENGINEERING AND MINING JOURNAL* of April 18, 1908, says: "The only remedy in the first instance will be proper ventilation; for this purpose I believe that the splitting of the air at each cross or room entry is the best system to follow, making crosscuts between entries and rooms as often as necessary to carry the air to the working faces at all times."

President William N. Page, of the West Virginia Mining Association, has also had something to say on this subject recently (*ENGINEERING AND MINING JOURNAL*, December 5, 1908). Mr. Page thinks that so far as the prevention of dust explosions is concerned, slowing down the ventilating currents to a velocity at which they will not carry dust in dangerous quantity, is the most effective measure against the dust danger. It is evident, however, from Mr. Page's following remarks, that what he believes in is not less, but better ventilation. He says:

"The tendency heretofore has been to regulate by statutes the specified volumes of air per minute for each man, animal and light, without any limit beyond the statutory specifications; the mine inspectors have all considered high velocities as the most desirable attainment, the higher the better, with an eye single to firedamp and pure air for the miner. It seems to me, however, that the time has come when the law makers and mine experts should study consequences, as too much of any good thing must always be harmful.

"Instead of forcing 200,000 cu. ft. of air per minute through restricted airways and passages by a single fan, under sufficient pressure to permeate every part of a tortuous mine, necessitating high velocities in many passages, I would suggest that the current be split as often as possible, and a number of auxiliary fans be substituted for one powerful single unit. Five fans delivering 40,000 cu. ft. will be preferable to one delivering 200,000 cu. ft., not only because of the slower velocities, but from an actual saving of power through less friction. Such small units

placed within the mine will operate as force and suction at the same time, and since electricity is now almost universally employed underground, there is no mechanical or other difficulty in the way of installation. The cost of the small units combined will be little, if any, greater than a single unit of equal capacity.

"Where there is more than one intake and outcast, there is no problem involved, and in shaft mines with limited entrance, the difficulties would be neither great nor costly, as the necessary intake and outcast where the velocities might be high, could be easily isolated from all danger. In other words, the currents could be passed through auxiliary fans and slowed down, just as an electric force can be stepped up or down through a rotary converter. With such an arrangement, a uniform volume of air, under slow velocity, could be more satisfactorily distributed across all working faces, and a small motor-driven fan could be moved from place to place, with little loss of time or money."

With the introduction of comparatively small centrifugal fans of the turbine type, the ventilation of mines in such a way as that recommended by Mr. Page no longer presents the insuperable difficulties that existed in the days when the Guibal fan was the best known means of mine ventilation. Among other advantages of the newer types of fan, their speed and output can be nicely regulated in accordance with special demands. There appears, therefore, as has been said above, no reason for fearing "too much" ventilation. There is, however, reason to demand ventilation that will not merely supply a fixed volume of air, but which will be adapted to the special requirement of given mines, and be so arranged as to reach those parts of mines that are especially dangerous, instead, as often happens at present, of being mainly confined to areas of the mine that perhaps need no ventilation at all to prevent gas or dust explosions.

Explosions in Coal Mines

BY MEL BUTLER*

Some time ago in these columns I expressed the belief that it was impossible for mechanical devices alone to make coal mines free from explosions. The recent disaster at Marianna, where every effort had been made to perfectly equip the plant mechanically, and where the property was known as the "model" mine, further confirms my opinion.

Improved living conditions will not immediately produce more intelligent and responsible people. The standard of the coal-mine worker has for years, been go-

ing lower, and it will require years to make an appreciable general improvement.

It is hard to understand why so many coal-mining companies will spend any amount of money for equipment to make the mines safe and to reduce costs, but will not put on shot-firers, allowing indiscriminate firing by all miners regardless of their experience. Prevent "blown-out" shots, and mine explosions will rarely occur. Certified fire-bosses, mine-bosses, engineers and superintendents do not prevent explosions, and alone, never will; the unions have not accomplished anything in this respect, being solely absorbed in the membership list and the collection of dues.

Apprenticeship is the system required to make better mines and thereby safer miners; this, and being required to pass a suitable examination before a certificate is issued, will teach them what should be done, as well as what should not be done, to prevent explosions, and also reduce the number of accidents at the face. I sincerely hope to see something on these lines before long.

Patent Legislation in Washington

SPECIAL CORRESPONDENCE

At an important meeting of the House Committee on patents on Dec. 12, the subject of patent legislation for this session was considered in executive meeting with the Commissioner of Patents. It was determined to prepare and place before Congress a bill relating to the so-called "manufacturing question." Specifically the bill is to provide some means for encouraging the manufacture of goods protected by American patents in the United States. In case foreign owners of American patents manufacture exclusively abroad the goods protected by such American patents it is designed either to provide for the forfeiture of the patent rights, or else to leave the maintenance of the patent rights to private litigation making it a special defense against infringement to show that the goods protected by American patents are not produced in this country, but are exclusively manufactured abroad.

New Zealand Production

The Mines Department states the exports of gold from New Zealand for the nine months ended Sept. 30 at 382,681 oz. bullion in 1907, and 390,442 oz. in 1908; an increase of 8361 oz. The bullion reported this year was equal to \$7,515,238, or 363,583 oz. fine gold. Silver exports for the nine months were 1,207,381 oz. in 1907, and 1,238,317 oz. in 1908; an increase of 30,936 oz. The silver comes chiefly from the gold mines of the Ohinemuri district.

Is Coal Dust, as Such, Explosive?

A Study of the Chemical Reactions That Occur in Dust Explosions, and a Percentage Estimate of Fatalities Due to Falls of Roof and Side

BY AUDLEY H. STOW*

Of all the perplexing questions that have puzzled the minds of the most intelligent observers, at one time and another, dust and dust explosions, probably compare quite favorably in the number of widely diverse, and often clearly contradictory theories that have been advanced, for the solution or explanation of the various phenomena accompanying these occurrences.

In attempting to forge a chain of deductions, to prove a certain theory, or to contravert the opposition theory, one of which must be wrong, we only too often find that there is a missing link, and that we lack the necessary information to arrive at a definite conclusion, thus leaving the adherents of the two theories secure in their loyalty to their views.

The amount of evidence to prove that dust, in the absence of all gas, has exploded, on almost numberless occasions, seems amply sufficient to settle the question; yet it is also claimed by many, at least this is the impression, that dust is not explosive, *per se*. We now have in addition Mr. Haas' theory that dust, as such, is not explosive. This appears rather a technical distinction, interesting if it is true, but not clearly having a practical bearing on the question as to whether dust is, or is not explosive.

It is not quite clear from the arguments in support of the last-mentioned theory whether it is conceded that explosions have resulted from dust in which no fire-damp was present, or whether the position is taken that a dust explosion is an impossibility, in the absence of all gas, as such, immediately prior to the instant of ignition. However this may be, the line of argument advanced in support of this addition to the already long list of our theories on dust, is one of some interest, and appears to admit of being carried still farther, although unfortunately we lack the necessary information to reach a definite conclusion, thus leaving the result still a matter of personal opinion.

The quantities used by Mr. Haas are substantially correct, for the purpose, although somewhat different values appear more nearly correct, at least in regard to the relative weights of air and coal, if we are to use the point of maximum explosive force.

The relative quantities will also depend on whether we assume that the

fixed carbon does not take part in the reaction, or whether we assume that the dust is entirely consumed. In many dust explosions the deposits of coke are certainly extensive, yet it will be assumed for the present that such deposits are due to the lack of air, or the excess of dust, as may be preferred rather than the inability of the fixed carbon to take part in the reaction.

THE REACTIONS THAT OCCUR

Again, the relative quantities will depend somewhat on the variety of coal under consideration, more particularly in regard to the per cent. of volatile matter. As the exact chemical structure of coals is far from having been exactly determined, we will assume certain structures that agree, near enough with observed results.

If the coal has such a structure that when subjected to destructive distillation, it yields 3 atoms of fixed carbon and 1 molecule of methane, we have, disregarding the ash, 31 per cent. volatile matter and 69 per cent. fixed carbon.

Air may be considered as 1 atom of oxygen, and 4 of nitrogen; we thus have:

or 1 part by weight of coal to 13.84 parts by weight of air.

If we assume that the coal consists of 6 atoms of fixed carbon to 1 of CH_4 , we have 82 per cent. fixed carbon and 18 per cent. volatile matter, exclusive of ash.

or one part by weight of coal to 13.09 parts of air.

J. T. Beard, in his "Mine Gases and Explosions" gives 1 to 9.57 as the maximum explosive mixture. If we take the specific gravity of methane as 0.559, we have

$$0.559 : 9.57 :: 1 : X, \text{ therefore } X = 17.12.$$

or 1 part by weight of marsh gas to 17.12 parts of air.

It has been figured that 1.359 lb. of coal containing 20 per cent. volatile matter, will replace 1 lb. of marsh gas; we thus have

$$1.359 : 17.12 :: 1 : X, \text{ or } X = 12.69.$$

That is, 1 part by weight of coal of the composition stated, will require 12.59

parts of air. For present purposes, 1 part of coal to 13 of air is near enough.

If we take the specific gravity of bituminous coal as 1.2, the weight of a cubic foot of water as 1,000 oz., and the weight of this same volume of air as 1.2 oz., we have that the weight of a given volume of coal is 1,000 times that of an equal volume of air. As an amount of air 13 times the weight of the coal is necessary to maximum explosive force, we thus have 13,000 volumes of air required per volume of coal.

STANDARDIZATION OF SCREENS

The tendency seems to be to adopt the 200-mesh screen as the definition of dust proper. The standardization of screens has been discussed at intervals, for some years past; however, there appears to be difficulties, largely mechanical, in the way of the desired degree of exactness of the smaller sizes. As proposed by the committee in standardization of screens, appointed by the council of the Institution of Mining and Metallurgy, London, the aperture of the 200-mesh screen should be 0.0025 of an inch, corresponding to the 0.0002083 part of a foot. The radius of the sphere that would exactly fit this aperture would be 0.0001042. In order that the sphere should pass through the screen without clogging, a certain amount of clearance will be required. If we allow 0.0000042 for clearance, we thus have the 0.0001 part of a foot as the radius of the largest sized sphere that will pass through a 200-mesh screen.

If we denote the radius of the sphere by r , and the radius of the hollow spherical shell, surrounding the particle of dust, and having 13,000 times the volume of the sphere, by R , we have

$$\frac{4}{3} R^3 = 13,001 \times \frac{4}{3} r^3, \text{ or}$$

$$R = r \sqrt[3]{13,001}, \therefore R = 23.51 r.$$

The radius of the hollow spherical shell of air surrounding the particle of coal dust, expressed in fractions of a foot, is thus 0.002351.

It need hardly be said that the relation of the radii would have been the same, had the sphere been one foot for instance, in diameter, but we are not discussing lump coal.

We have now reached the point where further exact progress is barred by the lack of exact information. We can only surmise the possibilities in the case.

It may be argued with good reason, that

*Mining engineer, Maybeury, West Va.

in the spherical shell of air, the radius of which is 23.5 times that of the particle of dust, it is a physical impossibility for all the atoms of oxygen to be in actual contact with the particle of coal dust. Quite probably this is correct, yet there appears to be at least a few words that can be said in favor of the opposite view.

If the atoms of oxygen and nitrogen were of the same relative sizes, and the same distance apart, as the molecules of coal, we would have approximately 13,000 of the former in the spherical shell surrounding our one particle of coal dust. Necessarily only a negligible proportion could be in actual contact with the coal.

As far as noticed, we have no definite information as to the relative sizes of the atoms of the different elements. It appears somewhat plausible that there is a considerable difference in the relative sizes of the atoms of oxygen in the air and the molecules of coal.

It seems not improbable that the molecules of water and the molecules of coal are at least approximately about the same size. In the same way, the atoms of oxygen, as liquefied oxygen, are possibly of somewhat the same size as the molecules of coal. It however requires about 320 atmospheric pressures to liquefy this gas. If the atoms of oxygen, when the gas is in the liquid state, are the same size as the molecules of coal, the atoms of oxygen in the gaseous state should occupy 320 times the space they do in the liquid form. They are not, however, necessarily 320 times as large. On this basis, there could be only about $\frac{1}{320}$ the number in the spherical shell that there would be, if the atoms of oxygen occupied only the same space as the molecule of coal. This would equal 40 atoms of oxygen and nitrogen per molecule of coal.

We, however, get a somewhat different figure by another method. Suppose instead of a sphere of coal 0.0002 ft. in diameter, the coal has been reduced in size until we have a single isolated molecule of coal. The relative proportions of the radii, and the relative volumes, will remain the same.

UNDER CERTAIN CONDITIONS, COAL DUST, AS SUCH, CAN EXPLODE.

According to our formula for coal containing 20 per cent. volatile matter, we have that a molecule of coal contains 11 atoms of carbon and hydrogen together with 80 atoms of oxygen and nitrogen. If, however, we assume that the oxygen and nitrogen in the atmosphere exist in a sort of a double state, as molecules consisting of 2 atoms each, we have 40 molecules of oxygen and nitrogen, as before.

If we have only 80 atoms in our spherical shell, the contents of which is 13,000 times that of the molecule of coal, it seems reasonable to suppose that they must be in a state of intense vibration,

while also having a range of motion many times greater than their actual diameters. If such a state of affairs actually exists, it is not unreasonable to suppose that every atom of oxygen and nitrogen actually touches the molecule of coal, not necessarily at the same moment, but in such rapid succession that the intervals between are so close together as to be far past our comprehension. For all practical purposes, all the atoms of oxygen would be at all times in immediate contact with the molecule of coal. Under these circumstances, no reason is evident why coal dust, as such, cannot explode, depending, however, somewhat on the size.

If now we replace our single molecule of coal by a particle of dust containing 5 molecules, we have, on the assumed basis, 200 molecules of oxygen and nitrogen in the surrounding spherical shell. In this case, it is still possible that all the molecules of oxygen come into actual contact with the particle of dust, although the interval between the time any one molecule of oxygen comes in contact with the particle of dust, and the time of its next contact, is probably much greater.

If this process be continued until we have 13,000 molecules of oxygen and nitrogen in the spherical shell, we have, in one way, reached the same state of affairs as if the molecules of oxygen and nitrogen had occupied the same space as the molecule of coal. One point of difference however is, we should have a particle of coal dust containing approximately 320 molecules of coal, and in the other case, only a single molecule.

If it be thought plausible that a single molecule of coal can result in an explosion, whether the explosion result from the molecule as a whole, or from its component parts, it seems that one point has been made. It has long been conceded that dust becomes dangerous in proportion to its state of subdivision. The foregoing theory is a possible explanation of the observed fact.

All that has been said may, however, be absolutely disregarded, without seriously impairing the case of the prosecution against the supposed deduction, on the score of relative volumes, that an explosion of coal dust is an impossibility. It is possible that no such deduction has been intended. This may altogether be a mistake, although if it is not, the line of argument on the score of relative volumes appears seriously defective in one important respect.

This may be illustrated in the case of our particle of coal dust containing 320 molecules of the carbon compound usually known as coal, by introducing within the spherical shell containing 13,000 molecules of oxygen and nitrogen, 300 additional particles of coal dust, preferably of the one molecule size, in order to prevent crowding out too many of the molecules

of oxygen and nitrogen. We thus have a large excess of dust, it is true, over and above that required from a chemical standpoint, yet as far as the molecules of oxygen being in practically direct contact with the particles of dust, it appears at least plausible that we have much the same situation as with the one molecule particle of dust in a spherical shell containing 40 molecules of oxygen and nitrogen.

In other words the interesting relation of the relative volumes of coal and air, necessary to produce an explosion, appear to prove, not that an explosion is an impossibility, but that a large excess of dust is required, depending, however, upon the sizes of the particles of dust, measured in molecules, as well as upon the absence of such internal motion as results from a blown-out shot.

DISTILLATION OF VOLATILE HYDROCARBONS DURING AN EXPLOSION.

Bituminous coal certainly gives off volatile hydrocarbons at a temperature below which the coal actually begins to burn. In the case of dust, which is in the act of exploding, if the fixed carbon did not take part in the reaction, the distinction that dust as such, does not explode, would have practical significance.

As far as we know, however, it is not at all clear that the fixed carbon should not, or probably does not, take part in the reaction. If the temperature of the dust, and of the air in which it is suspended, is sufficiently high to distill the volatile hydrocarbons, previous to the actual ignition, certainly the combustion of the hydrocarbons thus distilled will raise the temperature of the air, and the resulting coke, to a temperature far above that necessary for the combustion of the latter substance. It is hardly supposed that there is any question that the initial temperature may be that found underground, and yet the combustion of the distilled hydrocarbons be sufficient to raise the fixed carbon to the point of ignition. If coke is deposited in quantities, as it often is, it seems more plausible to assume that the supply of oxygen was insufficient for the combustion of all the dust. That such hydrocarbons as were volatilized but not consumed, owing to lack of air, remained in suspension, while that portion of the fixed carbon not consumed from the same cause, was deposited, owing to its greater specific gravity.

If the fixed carbon does not take part in the reaction, we would thus have two varieties of gas explosion. Even in this case, it would be appropriate to retain the name, dust explosion, as applied to that variety of gas explosion in which the hydrocarbons were distilled from coal dust suspended in air.

If the fixed carbon does take part in

the reaction, it would comply more nearly with the facts to describe it as a gas and coke explosion, although clearly, in this case, an explosion which has resulted from dust suspended in air.

EXCESS OF AIR AND WATER THEORY

It has been estimated that the total number of deaths resulting from explosions is 5 per cent. or less, of the total number of fatalities, while we have it on good authority that the deaths resulting from falls of roof is 66 per cent. of the total. It appears to have been assumed that the 66 per cent. is due entirely to the slacking or disintegration of the roof by moisture, during the wet or summer season. As far as noticed we lack the data to mathematically demonstrate this view to be incorrect.

For the past 15 or 20 years it has been the general belief among old miners that it is advisable to pay the closest possible attention to the roof, as soon as the drops of moisture begin to appear in the spring. The time has been when these evidences of the approaching wet season, which make their first appearance at the drift month, were looked upon with no little fear and trembling. These sensations became a thing of the past, and were replaced by the growing conviction that there are no substantial grounds for the common belief of the miner that the summer season results in a material increase in the number of falls of roof.

That a large proportion of the slates which form the roof in many of our mines disintegrate rapidly on exposure to the air, on the slate dumps, cannot be denied; However, it is not clear but that the disintegration is evidence of the inherent weakness of the slate, the lack of cohesion of the latter being the true cause of the fall, and the disintegration being merely an indication of lack of strength.

It has been estimated that the proportion of slate or fireclay roofs in West Virginia, will average 90 per cent. or better. This appears somewhat high, if the territory adjacent to the Norfolk & Western Railway may be taken as an average for the State. This, however, is again one of the numerous points in regard to which it is only possible to give an opinion. The percentage will depend no little on the classification.

For present purposes, it appears justifiable to class as sandstones, all thin-bedded sandstones, or sandy slates. These latter usually form nearly as good roof as true sandstones. The slates, so-called, have been looked upon as more properly shales than true slates. Under this classification, for the territory stated, 50 per cent. sandstones, and 50 per cent. shales appears a probable figure. If, however, 40 per cent. sandstones and 60 per cent. shales, be taken, we have of the 66 per

cent. mortalities, about 40 per cent. occurring under slate or shale roof, and 26 per cent. under sandstone.

MANY FATALITIES FROM ROBBING PILLARS

Anyone who has spent much time on pillar work cannot but admit that about one-half of the fatal accidents occur in their recovery. Certainly the falls of roof on the pillars cannot be attributed to the effect of too high a percentage of moisture in the air. On this basis, we have 20 per cent. of the total number of fatalities that occur under shale roof, in other portions of the mines than the pillars.

Certainly "draw slate" is the cause of a large number of deaths each year. Draw slate, although a somewhat indefinite term, may be said to occur more generally in mines with sandstone roofs. Under this head is often included a layer of shale immediately overlying the coal, but less firm in structure than the shale next above, and from which it is usually separated by a parting plane. Even the novice in the business knows that the dreaded draw slate does not wait for the wet season. The number of cuts that the draw slate will stand, after the coal has been removed, can usually be counted on the fingers of one hand, although in a few sections or districts, if well timbered, it will stand for years. While most of the fatalities due to draw slate are properly chargeable to sandstone roof, certainly a small percentage at least should be charged to slate or shale roof.

We have still to account for the treacherous kettle bottom, which knows no law, and is no respecter of persons. Kettle bottoms and horse-backs occur in slate roof rather than sandstone. If we allow only 5 per cent., which appears rather an underestimate, for draw slate under shale roof, and for horse-backs and kettle bottoms under the same class of roof, we have but 15 per cent. unaccounted for.

If this 15 per cent. is due to the causes under consideration, excess of air and water, it is at least a possible view that the general effect should be that the roof would scale off in thin layers, as that immediately exposed to the action of the agencies under discussion, had become disintegrated, thus exposing a fresh surface. Certainly the appearance of a large proportion of the falls does not indicate any such action. Again we have a small proportion of coal top, upon which air and water appear to have no effect. If we deduct 5 per cent. for falls of coal top, and for falls in mines in which the top comes down in somewhat rectangular blocks, we thus have but 10 per cent., which may be charged to excess of air and moisture, although there are still other minor classes of accident that might be deducted.

These figures will probably be consid-

ered grossly incorrect by some, possibly by many; yet whether the per cent. be 10 or 66, it appears largely at least, chargeable to inherent weakness of our shales, in the territory mentioned. As far as it has been possible to judge from prospecting in advance of actual mining, as shown by nearly 1000 sections of record in Wyoming, Logan, Boone and Wayne counties, W. Va., Pike and Johnson counties in Kentucky, and a portion of Buchanan county, Va., the roof has appeared to average much the same as in the territory adjacent to the Norfolk & Western Railway, in which mining is being carried on, in Mercer, McDowell and Mingo counties.

It is by no means contended that strata immediately overlying the coal are not in instances, seriously affected by water. Such is understood to be the case in some of the mines in the anthracite field of Pennsylvania. A roof that appears to be so affected has been noticed in the vicinity of Middlesborough, Ky., however the impression is that these are the exception and not the rule.

If the 66 per cent. of deaths was due to the excess of water alone, we would have this situation: From the 34 per cent. due to other causes 5 per cent. due to explosions would have to be deducted, leaving 29 per cent. equally distributed throughout the year, or 15 per cent. in winter during the dry season, the remaining 14 per cent. occurring during the wet season, which with the 66 per cent. due to moisture, would make 80 per cent. during the summer and 15 per cent. during the winter, exclusive of explosions. Any such increase confined entirely to one season, could hardly have passed unnoticed. That a difference in the volume of air passing can have any material effect of itself, other things being equal, appears less plausible than the excess of water theory.

The disintegration on the outside is more likely due to the daily changes of temperature than to exposure to the air, which would occur in the mines were the fan not running.

It is realized that the several views herein expressed are only personal opinions, which may in part at least be seriously incorrect. Yet if mining men and engineers would aid, with their ideas and experiences, we should in time make material progress in the control of dust.

In hydraulic mining in Victoria, Australia, gravel is being elevated to great heights. At the Creswick Black Lead the tailings are being raised to a height of 102 ft. by a three-port runner pump in one lift, the depth of gravel worked being 70 ft. At the Cock's Pioneer mine, where a 80-ft. bank of gravel is being worked, the tailings are being raised to a height of 123 ft. in two lifts.

Utilizing Blast Furnace Gases at Gary

A Great Power Plant to Be Operated by Gases Which Were Formerly Considered Waste and Allowed to Escape. Gas Engine Development

SPECIAL CORRESPONDENCE

Frequent references have been made in the columns of the JOURNAL to the utilization of blast-furnace gases in furnishing power. In this development in iron making German and Belgian metallurgists have been far ahead of those in the United States. The latter, however, have taken up this question with energy. The first important plant of this description installed in this country was at the works of the Lackawanna Steel Company at Buffalo. The metallurgists of the United States Steel Corporation some time ago began to study out the application of this economical development, and have used it in the alterations and improvements made at the various Carnegie works at and near Pittsburg, and the Illinois works at Chicago. The most important use of blast-furnace gases, however, is found at the new works of the Indiana Steel Company at Gary—a general description of which was given in the JOURNAL of Dec. 26—where the largest plant of the kind ever designed or built will shortly be in operation.

VOLUME OF GAS AVAILABLE

It is unnecessary here to go into the general subject of the utilization of the waste gases. As a general rule, only part of them have been used heretofore, in two ways: First, in heating the stoves through which air for blast is passed to raise its temperature; and second, to a small extent, in boiler furnaces for making steam. These uses are still continued, but the balance of the gases which in most blast furnaces is allowed to escape, are here used to generate power through the medium of the gas engine.

Speaking generally, a 500-ton coke furnace of the type built at Gary will pass off in 24 hours about 2,800,000 cu.ft. of gas. When all the 16 furnaces are in operation, this will give about 44,800,000 cu.ft. daily. Of this supply approximately 30 per cent. will be used for heating the blast stoves, 7.5 per cent. under boilers for raising steam, while 5 per cent. will be consumed for various auxiliaries, or lost in the cleansing process. This leaves 57.5 per cent. of the total to be used in generating power, of which 12.5 per cent. will be required for the blowing engines, leaving 45 per cent. of the total available to generate power for the operation of the works. This 45 per cent. will be equivalent, when all of the 16 furnaces are in blast, to over 200,000 horsepower.

CLEANSING THE GAS

The first step is to free the gases from

the large quantity of dust carried over by them from the furnaces, and also to cleanse them from other impurities so far as possible, and to bring them into proper condition for use in the gas engines. The gas from each furnace, escaping from four outlets, passes into the two downcomer pipes, which lead into a reservoir 30 ft. in diameter by 40 ft. high, called the dry-dust catcher. Then a considerable part of the impurities settles to the bottom, and the gas passes into another large pipe, which leads upward some distance to increase the quantity of dust dropped and then turns down again, emptying into a supplementary tank 14 ft. in diameter by 25 ft. high, one of which serves each pair of furnaces. This structure not only provides an additional dust catcher, but also acts as a valve, being divided into two compartments partially filled with water. By increasing the height of the water in either one, the furnace on that side can be cut off as desired, and there will be no back flow of gas from the mains beyond. The two chambers of this tank discharge into a pipe 10 ft. in diameter, which carries the gas and remaining impurities into the primary wet washers. There are three of those to each pair of furnaces and each has sufficient capacity to take care of the gas from a single furnace, thus providing a spare washer for use while one is being cleaned or repaired. The primary washers are cylindrical in form, with cone bottom and cone top, and are about one-third full of water, a proper overflow maintaining the required level. Here the gas and dust are discharged against the surface of the water from pipes with fluted edges and then escape around these edges into openings from a larger main. At this point a small percentage of the gas is diverted to special furnaces under a battery of Rust boilers used for making steam, and about 30 per cent. is taken for heating the stoves. The remainder continues on to the secondary washers. First of this group are the vertical scrubbers, drums about 14 ft. in diameter by 50 ft. high. A torrent of water cascades down through it, and from near the bottom of the drum comes the stream of gas against it. Rising to the top the gas again passes on into what are known as Thiessen washers, of which there are four to each pair of blast furnaces. In each of these it is led between the wall of a cylinder and a revolving drum, armed with a series of paddle-like blades. A stream of water is spread into a film on the surface of the cylinder and the whirling drum throws such impurities

as the gas still holds out against the water film, where they are caught and held. From these final washers the gas is conveyed under slight pressure to the holders, each of which has 200,000 cu.ft. capacity; from there it goes, as required, to the electric-power station and blowing-engine houses. The water for the various processes described above is furnished by four large Platt turbine pumps.

THE BLOWING ENGINES

For the eight furnaces thus far erected there are two blowing-engine houses. One is 600 ft. long and 104 ft. wide, and the other is of the same width, but only 530 ft. long. The difference is due to the fact that the first house includes a central pumping and hydraulic power plant, equipped mainly by the Snow Steam Pump Works, of Buffalo, N. Y. Besides gas engines each house contains two steam-driven Tod blowers, but, when the plant is in full operation, these will not be used, but held in reserve in case of accident.

Each of the 16 blowing engines consists of a horizontal, twin-tandem gas engine of 2500 horsepower, having cylinders 42 in. diameter by 54 in. stroke, and two direct-driven blowing tubs having a capacity to deliver 30,000 cu.ft. of free air per minute against a pressure of 18 lb. per sq.in., and so designed and proportioned that they can be operated at any pressure up to 30 lb. These blowing tubs are of the Slick type, the patents for which are controlled by the Allis-Chalmers company. By using this type an inlet-valve area of 25 per cent. and over is easily attainable, thus insuring that the cylinder will fill completely at any speed at which the engine is able to operate it. The gas and air cylinders are located at opposite ends of the engine frame. Eight of these engines were built by the Westinghouse Machine Company and eight by the Allis-Chalmers Company.

THE GENERAL POWER STATION

The power station, which is 966 ft. long and 105 ft. wide, with forty-two 23-ft. bays, is adjacent to the blowing-engine houses and between the blast furnaces and open-hearth furnaces. This places it advantageously for fuel supply and insures minimum lengths of transmission lines to the various departments using electric power.

In this central station are installed 17 horizontal, twin-tandem, double-acting gas engines, turning at a speed of 83¼ revolutions per minute; 15 of which are designed

for coupling to alternating-current generators and two to be connected to direct-current generators. The former are 25-cycle, three-phase, 6600-volt machines, and the latter deliver current at a pressure of 250 volts. The engines have a rating of 4000 horsepower and the generators 2000 kw., but they are capable of carrying continuously 30 per cent. overload. The 17 units were built complete by the Allis-Chalmers Company. These are the largest engines in the world to operate on blast-furnace gas, being practically duplicates of the units built for the Illinois Steel Company, operated in parallel. The successful working of that plant insured the success of the Gary installation.

FEATURES OF THE ENGINES

The distinctive features of the engines are the simplicity of design, the solidity of construction and the quiet operation. Maximum overloads are handled in practice as easily and with the same freedom from vibration that characterizes their operation under normal condition. While the engines are, as a whole, exceptionally rigid and heavy, the weight is concentrated in the frame cylinders and tie pieces in the direct line of stresses to which an engine of this type is subjected. In the frame is illustrated the principal difference between European and American design. This frame is designed for a side crank in place of the double-throw crank which represents the standard practice abroad. The stresses transmitted to the frame in a side-crank engine are very great, but, even in the largest sized gas engines, they are no greater than builders have for many years successfully provided for in steam-engine practice.

The jaw, which is subjected to peculiarly severe stress, is made in a form to insure maximum strength of the casting and is further strengthened by two steel tie bolts carried above the shaft, which are made of sufficient size to carry their proportion of the load without appreciable elongation. This construction eliminates entirely any bending stresses in the frame at this point. The engine frames weigh approximately 90 tons each, and one-half of each frame is buried in the foundation, in order to raise the floor line to a point which will make the rods on the valve gear readily accessible.

The floor space occupied by one engine is 70x44 ft., and the weight approximates 1,700,000 lb. The cylinders are 44 in. diameter by 54 in. stroke; the crank pins are 20 in. in diameter; the shaft is 30 in. in diameter in the bearing, and the fly-wheel is 23 ft. in diameter, weighing 200,000 lb. The pistons and rods are water-cooled, water being introduced at the center and flowing forward to a discharge in the frame for the front piston and backward to a discharge in the tail guide for the rear piston, each piston having its separate supply. For dismantling or for cleansing, the rod is made in two

parts, joined at the central slide, the rear half going out at the back of the engine and the other half going out through the frame, which is made open at the top for convenience.

THE VALVE GEAR AND OTHER DETAILS

The valve gear is located between the engines, concentrating on a twin-tandem in such a way as to make it very convenient for the operating engineer. The gear is of the builder's standard stratification type and the engine operates with constant compression, thus tending to insure smooth running under the highly variable loads to which it is subjected.

The igniters are electrically controlled and so arranged that the time of ignition may be regulated by a single hand wheel. Direct current at 80 volts is used in the ignition system. Duplicate independent igniters are provided at each end of the cylinder to insure prompt firing of low-heat gases and also to avoid the danger of shutdown due to short-circuit. The entire ignition system, from the motor generator set which furnishes the current to the electrically operated igniters, is solidly built.

The air-starting device consists of a small poppet inlet air valve at each end of each cylinder, operated by the layshaft. Air is admitted to each cylinder, in turn, at what would be the working stroke. As the high compression carried prevents the engine from stopping on the dead center, this arrangement insures the prompt starting of even a tandem engine without the use of a barring gear. These engines being twin tandem will, of course, start from any position.

All wearing surface, including the main bearings, slides, crank and crosshead pins, are arranged for a continuous oiling system and the cylinders are lubricated by carefully timed admission of the cylinder oil, sight-feed oil pumps being used.

The exhaust from the gas engines is conveyed to a tunnel 12x9 ft., located immediately outside the building and beneath the ground level. This runs the length of the building and is provided at each end with a stack 9 ft. in diameter by 92 ft. high. The same method of muffling the exhaust is provided for the blowing-engine houses.

THE GENERATORS

The alternating-current generators are of a type developed by the Allis-Chalmers Company for use with these engines. The laminated stator core is held in a heavy box yoke designed to allow full circulation of air around all parts. The core punchings are held in place by means of dovetails and the armature windings are placed in open slots in the inner periphery of the stator core. The coils are held firmly in place by wedges and, on account of the open-slot construction, can be readily replaced in case of damage. The field poles are mounted on a cast-iron spider and so arranged that they can be removed; the

exciting coils are of copper strip wound on edge. The revolving fields are special in construction, with field poles of solid cast steel bolted to a heavy cast-iron spider; they can, therefore, be readily removed in case it is necessary to get at a field coil. The field windings are held in place partly by the projecting pole tips and partly by brass rings running completely around the rotor on each side and fastened to the top of the poles by long brass screws. The construction, combined with the solid poles, gives a large damping effect, prevents hunting and aids in securing parallel operation.

The direct-current generators have also been designed with particular regard to this service, but in general are similar to the Allis-Chalmers standard engine type machines.

In connection with the generators the company has furnished Cutler-Hammer remote-control field rheostats and field switches. The controlling apparatus is located in the basement as near as possible to the generators and is operated from the bench board located in the power-house gallery. These rheostats are of a unique design, being what the manufacturers call the crosshead type. They are driven by means of vertical motors and are provided with automatic devices which insure the stopping of the motor at either limit of the crosshead travel; that is to say, either when all resistance has been cut in or cut out of circuit. Means are provided, also, for operating these field rheostats by hand in case of damage to the motor.

THE ELECTRIC MOTOR DRIVE FOR THE PLANT

The power generated will be distributed throughout the works and used to operate the heavy induction-motor-driven rolls, the tilting and feed tables for the various passes, the hot saws, hot and cold pull-ups, hot rolls, transfer tables, straightening and drilling machines, cold saws, elevators, conveyers, pumps and a multitude of machines and mechanical devices auxiliary to the operation of the rolling mills. Several of the motors built by the General Electric Company for these works are of 6000 h.p. each, being designed for driving the rolls, and from this they range in size down to machines of the smallest capacity used to operate switches in the power house.

The problems of control presented by the multitude of motors installed at this plant involve many interesting features, the solution of which was largely intrusted to the engineers of the Cutler-Hammer Manufacturing Company, of Milwaukee, and the automatic devices now installed at Gary represent the most recent developments in electric control as applied to steel mill machinery.

The electrical system as a whole is subject to central control at a switchboard operated from a gallery 16 ft. high. This switchboard, which was designed by the

Western Electric Company, has the usual complement of instruments of standard types.

STORAGE BATTERY

To aid in securing maximum economy under heavy fluctuations of load, by utilizing the full value of the generating power of the gas, without regard to the amount of current required at any given time for the operation of the mills, a storage battery installation furnished by the Electric Storage Battery Company, has been housed in a two-story building 87 ft. long by 47 ft. wide, located near the power station. The batteries will be kept charged as nearly as possible to their full capacity, in order to assist in meeting, for a considerable period of time if need be, any demands for excessive power made upon the gas-engine-driven generators. These can, in themselves, be heavily overloaded but the best power factor is, of course, to be secured at about their rated capacity. The battery also aids in maintaining, at light loads, a constant pull on the generating equipment. The control of the battery charge and discharge in respect to the 250 direct-current bus is effected by means of two motor-driven boosters which may be operated singly or in parallel.

The various motor generator sets, converter, etc., comprising this regulating system may be started and stopped from the bench board in the switching gallery by means of Cutler-Hammer remote-control starting apparatus and the fields of the various machines may be varied by means of remote-control field rheostats. One of these remote-control starters is notable for its size. It is used in connection with a motor generator set which is started from the direct-current end, and although the starting current is not abnormally high, the rheostat is designed to carry 10,000 amperes under maximum working load conditions. This is believed to be the largest ever made.

CONSTRUCTION OF THE POWER HOUSE

The subfoundation of the power station, as well as of each blower house, is a solid mass of concrete underlying the entire structure on the level of lake Michigan, and having a depth of 5 ft. Above this are separate foundations for each of the generating and blowing units. The arches forming the roof of the power station have a clear span of 85 ft., providing head room at the dome of 73 ft. above floor level. The station is served by two 50-ton cranes.

GENERAL CONSIDERATIONS

While the utilization of blast-furnace gases for the production of power has well passed the experimental stage, its adoption on so large a scale as that indicated above shows a high degree of confidence. The same thing may be said of the wide use of electric power throughout the plant, especially in the operation of the

large rolling mills. As was said in the previous article, the Gary plant possessed one great advantage, in that it has been built up entirely on a new foundation. There was no old plant to be considered, no alterations to be made, and everything could be designed absolutely in accordance with the latest practice. No other steel plant of the first order has been built in this country under quite the same conditions. Moreover, the designers apparently have not been limited by any considerations of first cost, but had a free hand in introducing any improvements which could be expected to reduce operating costs, and help to secure the maximum output of finished steel.

The Cullinan Diamond

SPECIAL CORRESPONDENCE

References have been heretofore made to the Cullinan diamond, believed to be the largest ever found. This stone, which was found in the Premier mine, near Pretoria in the Transvaal, on Jan. 26, 1905, was described and illustrated in the JOURNAL of March 23, 1905. It was too large to be sold to any individual purchaser.

Over two columns of the London Times, of Nov. 10 are devoted to a full description—the first authentic description published—of the history of this great diamond from the date of its discovery up to the completion of cutting and polishing. The diamond, as will be remembered, was presented to King Edward on his birthday Nov. 9, 1907, by the Transvaal government. Since its arrival in England the most elaborate precautions have been taken for its safety. In traveling to Amsterdam, where it was cut it was in the care of three guards and to avoid risks of shipwreck it was conveyed across the channel by the shortest route, the Calais Dover. Such elaborate precautions were not adopted in its infancy, so to speak, the stone having been forwarded to London from Johannesburg by ordinary registered letter post.

The cutting and polishing were carried out by the firm of Joseph Asscher & Co., of Amsterdam, who put up special machinery for the work. The stone was divided at first into two and subsequently into several pieces. The first cleaving of the stone was a delicate and risky operation. There are two processes for dividing diamonds, sawing and splitting. In splitting a steel knife is used to part the stone along its natural cleavage planes, and it is only along these planes, which are four in number and lie parallel to the faces of the octahedron, that the division can be effected. The diamond is held in cement at the end of a strong wooden stick. The operator holds the knife—a wedge-shaped piece of steel resembling a toilet comb in its general form and size—

in a groove, which must first be cut by a diamond, with his left hand, while in his right hand he delivers a blow with a steel hammer.

In splitting the Cullinan diamond the knife broke at the first blow, but the second blow was successful. It is always possible that this operation may break the stone into pieces not calculated on, owing to some flaw in the stone. There was therefore, much anxiety about the operation on this large stone. After splitting, the largest piece was cut and polished. The second piece was again divided and altogether a large number of brilliants were obtained. The following is a complete list of the stones with their weights:

1. A pendeloque or drop-brilliant weighing 516½ carats. The extreme dimensions of this stone are 2.322 in. long and 1.791 in. broad.
 2. A square brilliant weighing 309 3/16 carats; 1.771 in. long and 1.594 in. broad.
 3. A pendeloque weighing 92 carats.
 4. A square brilliant weighing 62 carats.
 5. A heart-shaped brilliant weighing 18¾ carats.
 6. A marquise brilliant weighing 11¼ carats.
 7. A marquise brilliant weighing 89/16 carats.
 9. A pendeloque brilliant weighing 49/32 carats.
 10. Ninety-six brilliants weighing 7¾ carats.
 11. A quantity of unpolished "ends" weighing 9 carats.
- The two larger stones are by far the largest in existence. The next in size is the Jubilee, weighing 239 carats, belonging to Werneher, Beit & Co. The famous Kohinoor weighs only 106 1/16 carats. All the Cullinan stones are, in spite of their size, of great beauty, being absolutely without flaw and of the finest blue-white color.
- The two larger stones are cut with 74 and 66 facets respectively; an innovation on the usual practice of cutting 58 facets.

Transvaal Gold Mines

Gold production in the Transvaal in November is reported by the Chamber of Mines at 614,371 oz. fine, which is 3373 oz. less than in October, but 64,570 oz. more than in November, 1907. The decrease from October was entirely due to the shorter month, the daily average having increased from 19,818 oz. in October to 20,470 in November, a gain of 661 oz. For the 11 months ended Nov. 30 the total output was 6,393,974 oz. fine gold, or \$132,163,443. This is an increase of 425,836 oz. over last year.

The total number of Kafir laborers at work in the mines Nov. 30 was 141,326, an increase of 2161 over Oct. 31. The number of Chinese was 12,203, a decrease of 10 only during the month.

Examining and Fitting up a Hydraulic Mine—II

The Construction of Sluices, Undercurrents, Grizzlies, Flumes and Penstocks, and the Building of Ditches Are Discussed in Detail

B Y H. A. B R I G H A M*

The details of the design of a sluice are shown in Fig. 1. For the bottom of the sluice $1\frac{1}{2}$ -in. boards will answer and for the sides $1\frac{1}{4}$ -in. The bottom planks should be surfaced on the top, the side planks should be left in the rough. The slits may be 4×5 in. for sluices up to 5 ft. wide, and 4×6 in. for wider sluices. The posts or standards are suitable if made from 4×4 in., and the post braces from $1\frac{1}{2} \times 4$ -in. timber. The bottom ties must be firmly laid so that no settlement will occur if the sluice should become filled with gravel. All joints in the bottom should close perfectly so as to prevent leakage of quicksilver and consequent loss of fine gold.

If there are springs along the line of the sluice, their water should not be allowed to back up and run over the top, since the pressure may force up the bot-

anchored down so that water outside will not lift it bodily.

PAVEMENT

If suitable timber may be obtained at reasonable prices, a block pavement is generally the most desirable, especially for the upper end of the sluice where the principal portion of the gold particles will settle, and where the pavement will have to be removed more frequently for this reason. If the sluice must be longer than is necessary for the simple saving of the gold, it may be desirable to pave the lower portion with other material, if a suitable kind is obtainable at reasonable cost.

Rocks or boulders make a lasting pavement and, under favorable conditions, may be desirable if they are very hard and of such shape that they may be securely

will probably wear at least five times as long as any block pavement before requiring to be changed by reason of uneven wear.

Steel bars and old railway iron make a very good pavement, for as much fine material and more boulders can be run over them than over a block surface. This iron pavement is generally more expensive, especially if the mine is situated at a great distance from a railway and lacks cheap transportation facilities. But it has the advantage of wearing much longer than blocks, and it needs less changing in consequence, an operation that always constitutes one of the largest expenditures and delays in hydraulic mining, especially where there are block pavements in long sluices.

BLOCK PAVEMENT

Blocks for pavement are generally made by sawing them from the trees in lengths suitable for the purpose for which they are to be used, say from 4 in. long, where a small head of water is to be used, to 12 in., or even more, where a large volume of water is run. These blocks are squared to such a size that a given number will reach across and just fill the sluice from side lining to side lining. Several different sizes may be used for the same sluice, but each size should be square, so that when replacing the pavement the blocks may be turned around in any manner best suited to make the smoothest surface possible.

It is very essential that the blocks be hewn squarely and truly and placed so tightly together that no crevice is left parallel with the current, for a small crack, more particularly if two or more are in line, will soon become larger by wear and will compel a cleaning-up and a change of the block system sooner than if this had been properly laid the first time; the wear, in that case, will be so irregular that it will be found most difficult to relay a satisfactory and smooth surface again without eliminating the uneven blocks.

SIDE LINING

The side lining of the sluice, shown in Fig. 2 as two 2×8 -in. planks on each side, has two purposes—to protect the permanent side of the sluice from being worn, and to hold the blocks and prevent them from rising and floating away. The thickness of the side lining will depend

FIG. 1. END VIEW OF SLUICE

tom, especially while cleaning up. Cutting a vent hole near the end of the side board, $\frac{1}{2}$ in. above the bottom board, with the bottom side of the hole sloped upward toward the outside of the sluice to prevent the quicksilver from running out, will overcome this difficulty. Several of these holes should be made along the sluice, especially where there is danger of water backing up on the outside.

A longitudinal cap or running board, say $1\frac{1}{2} \times 6$ in., should be placed on the top of the sides and nailed flush with the inner edge of the side board to prevent this from bulging into the sluice. The sides should be well braced against inward or outward bending. The sluice must be

held in place, particularly if they do not present too uneven a surface for the gravel and boulders to travel over. Rocks blasted by dynamite are not suitable for pavement, owing to the shattering effects of the dynamite.

It will be almost impossible to pave a sluice with stones and to make a surface so smooth and even that the same amount of gravel and boulders can be run over it that will run over a block pavement on the same grade; therefore the portion paved with rock should have a proportionate increase of grade. This is of great importance as the volume of gravel and boulders that can be run through the sluice depends upon the amount that can pass its section of least transportability; that is, that particular portion which has the least grade or the most uneven surface.

If hard rock is used in the pavement it

NOTE—Abstract of a paper read before the Technical Society of the Pacific Coast, and published in the *Journal of the Association of Engineering Societies*, October, 1908.

*Mining engineer, 1414 Filbert street, Oakland, California.

upon the width of the sluice and the quantity of water used.

With a narrow sluice and a small head of water, 1-in. lining will answer, while with a wide sluice and large volume of water, 2- to 3-in. lining is required, and this should reach sufficiently above the blocks to prevent the wear of the permanent side planking.

Boards are generally used for this purpose, but where there is a large amount of wear, blocks are sometimes utilized, especially if the sluice is located in a tunnel or at other places where it is inconvenient to change the lining. These blocks are made somewhat similar to block pavement by sawing them in $2\frac{1}{2}$ to 3-in. lengths from the tree, dressed to uniform sizes for top and bottom, and of

receptacle between the blocks ample in size to catch the gold. The thicker or broader they are, that is, the wider the space between the blocks, the greater and the more uneven will be the wear on the block edges, and, consequently, the rougher will be the surface of such a pavement after the blocks have been turned and changed around.

If large boulders, especially angular ones, be run over a pavement, it will become manifest that the wider the riffle, the more will the lower edge of the blocks be broomed and split off; this will make a very rough surface upon turning.

If the riffle pieces are too high, the receptacle for the gold will become shallow and sometimes obliterated when the pavement is worn thin. A $1\frac{1}{4}$ x2-in. riffle strip

against one of the side linings; thereupon a riffle stick is slipped under the side lining and pushed against the side of the blocks, raised up tightly against the bottom of the lining and nailed to each block with headless or small-headed nails, leaving $\frac{5}{8}$ in. of the nail projecting for insertion into the next row of blocks.

After one row is properly secured in the manner described, another row of blocks is placed across the sluices, the blocks are pried close together and set up tight against the side lining that was not wedged to in the case of the preceding row, thus breaking joints in the blocking system. The blocks are thereupon driven solidly on to the nails and against the riffle stick. Another riffle stick is inserted after this, and the process is repeated in

FIG. 2. PLAN, END VIEW AND SIDE VIEW OF UNDERCURRENT

any convenient length for the sluice. They are nailed to the side similarly to board lining.

RIFLE STRIPS OR BLOCK HOLDERS

The riffle strips or sticks answer two purposes also: To hold the blocks in place and prevent their floatage, and to create the intervening space, crosswise in the sluice, between two series of blocks, known as the riffle, whose office it is to hold the quicksilver and to catch and retain the gold particles.

The dimensions of the sticks vary under different conditions and according to differing opinions of miners. They must be strong enough to prevent the blocks from lifting and broad enough to furnish a

is sufficiently strong for a sluice 5 ft. wide; a wider sluice requires a $1\frac{1}{4}$ x3-in. strip.

LAYING A BLOCK PAVEMENT

A good method in laying a block pavement is to nail the side lining against the permanent side of the sluice, leaving the lower edge 2 $\frac{1}{4}$ in. above the bottom, where a 2-in. riffle strip is to be used; this will allow the end of the riffle strip to be inserted under it freely for the purpose of preventing the strip from lifting with the blocks when the water is turned on.

After the side lining is properly secured to the permanent side of the sluice, a row of blocks, all of the same size, is placed across it and wedged tightly together and

the same manner as just described and continued in both directions, up and down the sluice, provided there is no running water in it to interfere with the laying up stream.

After the entire sluice is properly paved and everything is in readiness for the water to be turned on, washing should be commenced with a small head of water, but when all the spaces are solidly filled with sand and fine gravel the full head of water can be used. In beginning to wash through a new sluice, where the ground on the outside is higher than the top of the pavement, caution must be used that the water does not collect on the outside to a greater height than on the inside, unless the sluice has already been properly

anchored or weighted down. Unless it has been filled solidly with rock or dirt to the top exteriorly, it should at once be made to overflow until the outside is filled completely with dirt, even with the top, if possible; if this is properly done, there is no further danger of the sluice's being lifted.

If the channel or face of the gravel deposit to be worked is too wide to be washed through a single sluice or cut, one or more branches in the sluice are necessary. These should start near the head of the main sluice.

The distance between these branch cuts or auxiliary sluices will depend upon the character of the gravel deposit; in the case of a deposit containing much hard clay to be broken up, or large quantities of boulders to be conveyed, these branches should be nearer together than in a case where the deposit is composed entirely of fine gravel and sand.

If the deposit contains adhesive clay, especially near its bottom, so that it cannot be worked separately and apart from the pay-gravel, then the branches should be close to each other and placed at such a steep grade that they will keep themselves entirely clear, allowing nothing to collect therein while washing this pay-gravel; or, what may be still better, the sluices should be built up as closely to the bank as possible, to secure the gold quickly from the clay, for the reason that the sticky clay has a decided tendency to take up all the gold that it may come in contact with, and it will carry all this, or nearly all that it has once picked up, entirely through the sluice and away from the undercurrents at a total loss to the mine. Where the deposit is very deep and extensive it may be advisable to hydraulic it off in two or more successive benches, as this will give a steeper grade for working the upper levels.

Speaking generally, a bank 250 to 300 ft. thick is as high as can be conveniently hydraulicked in one bench, although, under favorable conditions, it may be practicable to work with safety from a single bench a bank that exceeds 300 ft. in height. These conditions are: A large pressure for the giants; compact gravel, that will not run to any great distance from the bank when falling from the top in slides or avalanches, jeopardizing the safety of the giants; and also a wide open and roomy pit.

CLEANING UP

Cleaning up consists in removing the pavement, collecting and separating the gold from the sand and from the material lodged in the riffles or interstices of the sluice pavement. A clean-up is resorted to whenever it is deemed necessary to collect the yield of the mine. A clean-up is always required whenever the pavement is so worn by gutters that its sur-

face becomes so uneven that it cannot be relaid to a sufficiently smooth surface without the use of additional paving material.

While the pavement is being removed during a clean-up the flow of water is reduced to a very small quantity. The work is commenced at the upper end of the section to be cleaned up. As the pavement is removed, the fine material will be washed down slowly along the bared bottom of the sluice, leaving in its wake the separated gold, which is taken up in pans by scoops made for this purpose. The process is finished by panning the remaining sand from the gold, or amalgam, if quicksilver is used.

UNDERCURRENTS

Undercurrents should be placed wherever the hydraulic miner may deem them

other, make good grizzlies. The construction and location of these details are shown in Figs. 1 and 3.

Directly under these grizzlies, and parallel to them, a box from 2 to 4 ft. wide is provided, for the purpose of leading the water and fine material that has passed down between the grizzly bars into the undercurrent proper. The undercurrent should be from three to five times as wide as the main sluice, 24 to 36 ft. long, and should have about 50 per cent. more grade than the main sluice.

The number of grizzly bars, their distance apart, and the width and grade of the undercurrent will depend upon the amount of water used in the main sluice and the character of the gravel washed; the larger the head of water and the finer the material, the greater the number of bars, and the narrower the space be-

FIG. 3. PLAN AND END VIEW OF SLUICE

most effective. An ideal location for an undercurrent is created by placing a section of sluice 12 to 20 ft. long, and 1 ft. wider than the main sluice, at an elevation 2 ft. lower and about 10 ft. distant from the end of it. Near the lower end of this wide section of sluice, and at right angles across it, a set of steel bars, called grizzlies by the hydraulic miner, is laid. (Figs. 2 and 3.)

To prevent choking, these bars must be so placed that the space between them is wider at the bottom than at the top. Ordinary bars, 1x4 in., can be laid with a little care in this manner; from 10 to 20 of these, spaced from 1 to 2 in. apart are used according to the character of the gravel and the volume of water used in the main sluice. Steel bars, made for the purpose, with one edge thicker than the

tween them; also, the wider the undercurrent, the steeper the gradient. Where there is a very large amount of fine material, the undercurrent should have still greater width and grade than under ordinarily normal conditions. All the fine material, with sufficient water to run it over the undercurrent, must be allowed to pass through the grizzlies.

The purpose of the 2-ft. drop in grade below the main sluice is to reduce the current while passing over the bars; this will allow the fine gold to settle more readily and pass through between them, and it will also increase the life of the bars and make them last much longer than if they were placed at the end of the main sluice.

A good pavement or riffle floor for an undercurrent may be made of strips 4

in. wide and from $1\frac{1}{2}$ in. to 4 in. thick, lined on top with $\frac{1}{4}$ -in. steel plates held by countersunk nails. These riffles should be laid on edge, spaced $\frac{1}{4}$ or $1\frac{1}{2}$ in. apart; they may be laid either crosswise or longitudinally. Blocks also make a very good pavement.

If the richer portion of the gravel should be very hard or cemented, it is advisable to add more undercurrents if conditions will permit. To break up the cement, a high perpendicular drop is excellent. If on account of the filling of the dump with tailings that finally back up into it or some other cause, it becomes necessary to extend the main sluice from its lower end, the policy of placing an undercurrent at the lower end may be

pends on so many other contingencies that one must consider them all before deciding upon the practical amount of storage. The details of construction are matters of engineering that must be dealt with as they come up.

PRESSURE BOX OR PENSTOCK

A pressure box should be built at the head of the mine pipe-line. Fig. 4 shows a structure of this kind in plan and side and end views. It is more or less of a settling basin and strainer, intended to prevent sand and solids and also air from entering the pipe. A screen is provided to catch sticks, limbs and other floating debris too large to pass through the nozzles, while a sand box of ample proportions

to withstand the pressure in case it is fully choked with branches, leaves and other matter of this kind, for that is liable to occur during a windstorm.

The sand box should be amply large; it has a gate at the side to sluice out the sand and to turn the water out of the pipe whenever it may be necessary to dry it. If a larger head of water is used than can be accommodated by the sand gate, a waste-way must be provided near the bulkhead, so that the pipe may be dried quickly in case of accident, or in case there may be any necessity for changing the water suddenly.

MINE PIPE-LINE

Where it is possible to bring all the

FIG. 4. DETAILS OF PRESSURE BOX

questionable; still it is impossible to operate one midway in a sluice without sacrificing at least 5 ft. of the grade in order to get the water and the fine material that passes over the undercurrent back into the main sluice again.

WATER STORAGE.

The necessity of receiving or distributing reservoirs has been referred to before. They furnish facilities for regulating the head of water for the giants, and, in case it becomes necessary to turn off the water at the mine, they furnish an immediate supply of water when hydraulic mining begins again. The capacity of these reservoirs must be determined by the daily quantity to be used by the mine; this again de-

holds the sand and other heavy material and prevents that from getting into the pipe.

A spillway *O* is arranged on one side of the pressure box to prevent any damage from the surplus water. This should be wide enough to take care of any possible surplus due to clogging of the screen or variation of the flow. If the water is taken out of the main ditch directly into the pressure box, and the ditch continues past it, a spillway is unnecessary.

The screen *S* should be fine enough to prevent anything from passing through it that may choke the nozzles, and should be so constructed that it can be readily cleared. It should also be strong enough

water to one point to suit the conditions of head and locality, and in such a manner that one line may be made available for all the giants, a single line of ample capacity to convey all the required water is to be preferred.

A suitable gore or taper should be provided at the head of the pipe-line, at the point of intake from the pressure box, and this should be of such dimensions that the water in entering the pipe is not retarded. The lower the grade at the upper portion of the pipe-line, the larger and the longer the gore that will be necessary. In any event, it should be of ample size not to create needless friction, which reduces the pressure at the giants.

The main pipe-line should, if possible,

be laid away from the ground to be washed, and preferably, also, on a downward grade for the entire distance; long stretches of slack grade should be avoided, if practicable. As the pipe approaches the vicinity where washing is to be done, suitable branches should be inserted where required until the end of the main line is reached; there a gore must be inserted, tapering to the size of the branches, or a fork provided for two branches. Each branch should have a gate or cutoff.

The branches and gates should be placed as near to the commencement of operations as practicable in order that the working area of the giants may be extended from time to time without the necessity of moving the branch pipes and gates, which is expensive and causes much delay.

If, on account of the width of the gravel, two or more giants are to be used at some distance from the main line and away from the vicinity of the other giants, it becomes advisable to make the branch of the same diameter as the main line—with a gate attached—and to extend this branch line to the neighborhood of the giants; this will eliminate much of the friction due to long reaches of the smaller branch pipes.

All turns, gates and gores should be substantially braced to withstand the pressure, and the whole line should be anchored at short intervals to prevent its creeping downhill by expansion and contraction due to changes of temperature. Air valves of liberal area should be placed wherever they are needed along the line of the pipe to prevent collapse from any sudden withdrawal of the water below. There should be one at every point where the grade increases materially, and one below each cutoff, if the pipe below it has considerable grade.

It is necessary to provide more than one pipe-line where the contour of the country will not permit a satisfactory site for a distributing reservoir, but where one at a lower altitude is available; or, where a part of the water supply must be brought in a lower ditch system, too low to give a satisfactory pressure and yet furnishing valuable water; or, where the deposit of gravel to be worked is so extended and isolated that a branch from the main line cannot well be utilized for it.

In the case of two available pressures at different heads, the higher pressure system should be used for the greater part of the cutting and the lower one for regulating the flow to the sluices of the gravel taken from the softer strata, or from the material that has caved under the force of the higher pressure.

GIANTS

The number and size of the giants will be governed by the amount of water used, the width of the face of the gravel to be

worked, the pressure of the water at the giants, and the character of the gravel to be piped. It is better to use as large giants as practicable, for much more can be accomplished with one large giant than by running the same amount of water through two; besides, this saves the pay of one man.

The giants should be set as near the bank as safety from the falling bank will permit. If more than one is to be utilized at one point, they must be placed so that they will command as much of the bank as possible, and be in such a position that two or more may work together advantageously in a combined attack toward one point.

Deflectors are indispensable for the larger sizes of giants. A deflector is comparable to a delicate steering apparatus; by its aid the stream may be guided from one direction toward another. They are of two kinds. One consists of a short flexible coupling, inserted between the nozzle and the end of the discharge pipe; the other is a short section of pipe, a little larger than the nozzle, attached loosely to its end and projecting over the stream. Both of these deflectors turn on a gimbal joint, free to move in any direction; a lever is attached for moving the deflector.

A light pressure against the lever in any direction bends the stream slightly; this, in turn, moves the discharge pipe, which follows it, as it were, until the stream strikes the desired point. The pressure is thereupon released, and the unmolested stream becomes normal, retaining this direction until the deflector is moved again.

DERRICKS AND OVERHEAD TROLLEYS

If there are many large boulders that have to be broken up in order to run them through the sluice, and if the grade of the sluice is light and the dump room scarce, it may be advisable to use overhead trolleys or derricks for handling boulders, provided of course, that the conditions are favorable.

The derrick is an awkward and cumbersome thing to use around a hydraulic mine, especially if the bank is high and the pressure for the giants light, for it is necessary to have the derrick in the rear of the giants; this places it too far from its work, unless it has a very long mast and boom.

An overhead trolley is generally preferable, as this interferes little with the giants; and while its reach is restricted sidewise, it has unlimited range from the boulder dump in the rear to the face of the mine; also, it seldom needs shifting as the working of the mine progresses.

Where there are large numbers of boulders requiring blasting in order to dispose of them through the sluice, and where the dump room is restricted, and where the conditions are favorable for utilizing derricks or overhead trolleys, it

will be found much cheaper to dispose of these boulders in this manner than to run them through the sluice and choke up the dump.

HYDRAULIC ELEVATORS

Hydraulic elevators may be used to good advantage at times; indeed, in some cases the conditions are such that this is the only method by which hydraulic mining can be successfully carried on. In the case of valuable gravel deposits, free from quantities of large stones, pipe clay, stumps, etc., situated near or below the level of the surrounding country, which require removal by hand, if a large quantity of water under the required pressure is at hand, the hydraulic elevator becomes a necessity. The elevators are placed near the head of the main sluice and at a lower elevation, depending upon the height necessary to raise the gravel.

A hydraulic elevator, so called, consists of a pipe of suitable dimensions to convey or lift the water and gravel from a pit (sunk below the bottom of the deposit to be worked) into the main sluice above. It is generally built at a small vertical angle; the top reaches into the main sluice, while to its bottom in the pit is attached the elevator throat. A nozzle, set in line with the center of the elevator pipe, and parallel to it, is placed a short distance below the throat; water from the main pipe-line escaping through this nozzle forces the gravel and water from the pit up into the head of the main sluice.

One or more giants may be utilized for washing the gravel from the mine into the elevator pit in a manner similar to ordinary hydraulic mining, but all stones, clay, stumps, etc., too large to pass through the throat of the elevator, must be removed before reaching the pit. The elevator must be run continuously while the mine is in operation, for the pit becomes flooded immediately, whenever the water is turned off from the elevator nozzle. Any boulders, stumps, etc., that will run through the sluice can be elevated by this process equally as well as the fine gravel.

A giant under heavy pressure, placed at the lower end of the main sluice, may be used to great advantage in stacking or elevating the tailings wherever the dump room is ample in area but deficient in grade.

This giant at the dump may be utilized at any time, whether the sluice be running or not, whenever there is a surplus of water, or whenever it may be turned off from the mine. By using either a hydraulic elevator or a giant at the dump a larger grade for the main sluice can be obtained.

If there should be a depression in the bedrock of the mine below the grade of the sluice, or if the sluice as it extends ahead into the mine should pass over

valuable deposits, this gravel can be elevated and forced up into the sluice in a manner similar to the elevation of the tailings at the dump. This, of course, should be done after the top gravel has been worked down to the sluice grade.

The depth from which gravel can be elevated by this process depends upon the giant pressure. With a pressure of 300 ft. there should be no difficulty in forcing it up from a depth of 15 ft. or more.

DITCHES

The old hydraulic miner became an expert in the location and design of a ditch to convey the necessary water to meet his requirements. He was remarkably successful in overcoming difficulties of topography, and mechanical difficulties as well, and he usually overcame them without scientific instruments or scientific formulas, guided alone by his keen sense of the practical and by his ever-resourceful mind.

While the hydraulic miner knew by experience how to arrange the fall, the grade and the size of the ditch, the engineer now has recourse to the elaborate formulas that have been devised to help him. The Kutter formula and its modifications furnish engineers with the means to design ditches of proper capacity and gradient in any material. A few practical hints, however, by an old hydraulic miner will not be amiss.

In laying out the line of the ditch care should be taken to avoid any abrupt turn, unless this be absolutely unavoidable. In making a turn around a sharp point, the line should be carried into the hill somewhat, in order to insure a strong embankment. In turning around such points, it may be desirable to raise the grade for the top of the ditch to correspond to the height of the permanent roadway along the ditch, thus leaving a solid embankment to the full height of the roadway.

After the ditch is excavated the lower bank should be leveled down in such a manner as to leave a good roadway; this roadway should be considerably higher than the grade line so as to act as a protection against breaks, when, for any reason, small obstructions back the water slightly above the grade.

Flumes along the line of the ditch should be avoided as much as practicable, particularly if the water supply be partially or wholly cut off during the dry season; at such time the lumber will shrink and crack, damaging it more or less, and shortening its life considerably. Where conditions are favorable, a double wall may be built, filled between its two faces with clay or suitable dirt, by which a permanent bank is secured; and while this will increase the original cost, the extra expense may be justifiable.

Even in quite hard bedrock, it may be perfectly reasonable to do considerable blasting in order to avoid a flume and to insure a permanent ditch.

THE FLUME

This is so well known and has been used so extensively in California that it seems almost needless to refer to it here. But however that may be, practice is gained by contact and experience, and errors are frequently committed in the earlier history of a work that might have been avoided if it had been possible to impart the experience acquired by those who have had to do similar work.

The author, in his long contact with many different types of flumes, had under his immediate charge for several years one which so completely answered the requirements that it seems justifiable to call attention to it here. This flume was about 8 miles long, 4 ft. wide, 38 in. high, and lay on a steep hillside on a narrow bench that was graded just enough to afford a resting place for the inside of the flume; the outer side was held by props from the bank. This was the condition for nearly all of its length.

This flume (Fig. 5) was built of common yellow-pine lumber, with 1½-in. boards for bottoms and sides; 4x5-in. bottom ties, 6 ft. long; 2x5-in. top ties, 6 ft. long; and 2x4-in. posts, or standards, 4 ft. long; no braces; bottom and top ties mortised for the posts, which were unframed.

This flume was in constant use for 30 years. The portion that rested but partially on the ground was kept in repair at small expense, and its use could have been continued at a nominal expense for several years longer had the market for its water still existed. Aside from renewals due to accidental causes, practically all of the flume that rested on the ground was still the original construction after its long use, and the greater part

FIG. 5. DETAILS OF FLUME

Many of the old mining ditches bear testimony to his skill, to his perseverance and to his audacity. Mining and ditch building were almost synonymous terms in early days in California, and on the experience of the hydraulic miner much that we know today of the behavior of the flow of water in ditches and in pipes has been based. The investigations of Hamilton Smith are considered of great importance today, for Mr. Smith added no inconsiderable knowledge to what was at that time a rather barren field.

A ditch must convey the required quantity of water. To do so, it must have capacity and grade, or fall. These elements are interdependent and need to be placed in proper relation. The flow through a given cross-section of the ditch must be of a speed to permit the number of miner's inches to pass and yet not too swift to erode the material into which the ditch is cut.

The slope of the bank will be governed by the character of the ground along its course; the upper bank should be sloped back far enough so that the current cannot undermine it and cause slides or caves; accidents of this kind will occur during the rainy or flush-water season, if they occur at all, causing bad breaks, and entailing great expense, loss of water and delay while making repairs.

All trees liable to fall and damage the ditch ought to be cleared away. The surface below the ditch should be stripped of all brush, leaves, debris, etc., before commencing the excavation, in order that the material taken from the ditch and deposited on its lower bank may unite firmly with the undisturbed ground, making, after settlement, a solid and permanent bank; this will permit the miner to raise the water level in the ditch later on, thereby increasing the capacity considerably.

of it had not required the replacement of as much as a bottom tie in all that time.

It shows the possibility of a simple construction that one might not have ventured upon, preferring some more elaborate foundation at almost prohibitive cost. The risk proved the perfect practicability in the long and useful life of this simple flume.

A flume may be laid on an excavated bench on sills, projecting over the bank, or it may be erected on a partial trestle work for the support of the outer side. Gulches or deep ravines must be crossed on trestle bridges, as shown in Fig. 5. These bridges, when there is no other alternative in making the crossing, often become very formidable structures.

Short sections of flume should have the same area as the ditch, but long sections may be somewhat smaller, owing to the decreased friction of the water. It is questionable, however, whether a change of size is always justifiable, unless the reach of flume has considerable length, for the reason that it is inconvenient to keep various varieties and sizes of lumber in stock for repairs. If there is considerable repairing to be done, it is better to have only a few different sizes, thereby reducing the stock of lumber kept on hand for repairs. It may be quite practicable to plan the size of the flume in such a way that the same-size lumber answers for both sides and bottoms.

For a conventional flume of the type under discussion, the bottom boards and the sides, where the depth of water does not exceed 3 ft., should be 1½-in. planks; if much deeper, 2-in. boards will be necessary, especially for the bottom. For sills, or bottom ties, 4x5-in. pieces will answer for flumes up to a width of 4 ft. containing a 3-ft. depth of water; for a wider flume, 4x6-in. pieces may become necessary; for a flume 10 ft. wide, with a 4-ft depth of water, it will be well to make them from 6x6-in. lumber. For the top ties, or caps, take 2x5-in. pieces for a 5-ft. flume; 2½x6-in. pieces will answer for one 8 ft. wide where there is little snow. If much snow has to be provided against, the top ties must be correspondingly heavier.

For standards, or uprights, use 2x4-in. lumber for a 2½-ft. depth of water; 2½x 5-in. for a 3½-ft. depth; and 3x6-in. for water 4½ ft. deep. These sizes are all desirable, as they need no framing, the bottom and top ties being mortised through. The standards, cut to proper length, are driven firmly into the bottom tie, which acts as a brace, eliminating the ordinary diagonal brace necessary where the standard is set into a gain in the top of the sill. Another advantage over the latter is that, as the flume becomes old and weak from decay, it is much more stable and also more easily repaired, and it will last longer than the flume in which

the side ties are gained into the sills and caps.

In order to prevent the clear water from running over the sides of the flume abrupt turns are to be avoided as far as possible. Where a flume joins the ditch, especially at the upper end of the flume, a small gore should be inserted into one box-length, making it bell mouthed. This will prevent the water from backing up into the ditch, and it will have a tendency to prevent lumber, sticks and floatage from catching across its head. A flared box at the lower end of the flume having a swift current will prevent the ditch immediately below from undue erosion.

WASTE-WAYS

Waste-ways for turning the water out of the ditch in case of accidents, over-supply from rains or melting snow, or other causes must be provided at intervals along the ditch. They should be placed at points where the escape of the waste water will not result in cutting away the ground below the ditch and endanger its safety.

If the ditch is in a cold country where large amounts of snow will collect in it faster than they can be run through it, or where snow is likely to fill up the ditch when the water is not running, which would have to be sluiced out later, the waste-ways should be at frequent intervals, for it is necessary to get the water out quickly and in time before they become clogged up and break.

All waste-ways should be so constructed that the entire flow can be quickly turned out, and they should be so located that the water may escape without endangering any part of the ditch. Some provision should also be made to keep the freshest water from ravines out of the ditch; if it be impracticable to place these waste-ways at or near the ravines, in order to use them for that purpose, other means must be found to prevent this serious inflow.

In conclusion it may be said that the important point in hydraulic mining is to get as much material into the water as the current will transport through the sluice, and to convey this volume without interruption.

Gold in Western Australia

The Council of Mineowners reports the production of gold in Western Australia in November at 137,000 oz., an increase of 620 oz. over October, but a decrease of 8825 oz. from November, 1907. For the 11 months ended Nov. 30 the total gold output was 1,543,097 oz. in 1907, and 1,508,752 oz.—or \$31,185,004—in 1908; a decrease this year of 34,345 oz., or 2.2 per cent.

The Pittsburg Experimental Station

The station for the investigation of mine explosion of the technologic branch of the U. S. Geological Survey, at the Government arsenal grounds, Pittsburg, Penn., which was opened Dec. 3, 1908, comprises the following equipment:

Gas and dust gallery No. 1, 100 ft. long by 6 ft. 4 in. in diameter, has 15 sections of boiler-plate steel, three sections being ½-in. plate, the rest ¾-in. plate. In each section is a 6x6-in. window of ¾-in. plate glass and a release pressure door. At each lap joint inside is a circular angle iron for holding paper diaphragms to confine air and gas mixtures. Natural gas, from the city mains, containing about 80 per cent. methane and ethane, is used. It is measured by a meter, distributed by a 2-in. pipe, and mixed with air by an electrically driven exhauster. Coal dust is put on rows of shelves on both sides of the gallery.

In the concrete head, is a steel cannon 36 in. long and 24 in. external diameter, having a nickel-steel lining with a 2¼-in. bore 21½ in. deep. The charge is fired electrically from an observation room, about 60 ft. distant, having a window of ½-in. plate glass 6 in. wide and 37 ft. long, protected by external guards.

Gas and dust gallery No. 2 is a round boiler-plate tube, 10 ft. in diameter and 30 ft. long, open at either end.

The flame-testing apparatus comprises a vertical cannon, like that in gas and dust gallery No. 1, in a concrete base, below a boiler-plate stack having a vertical slit from which a light-tight conduit leads to a dark room where the length and duration of the flame from an explosive are photographically recorded on a rapidly-moving sensitive film.

The ballistic pendulum is a United States 12-in. mortar, weighing 31,600 lb., hung by steel rods from an iron beam having nickel steel knife edges resting on nickel-steel plates on massive piers. The length of swing of this mortar from a charge placed in a cannon like that in gallery No. 1, is a measure of the strength of the explosive.

A cable from Johannesburg, dated December 3, 1908 to *The London Mining Journal* announces details of an amalgamation plan embracing the Crown Reef, Robinson Central Deep, Crown Deep, South Rand, Langlaagte Deep and Pearl Central. When the merger is completed, the company will be the largest gold producer on the Rand.

According to *La Nature* a gold-bearing district has been discovered near Tamative, Madagascar.

The Tariff Hearings at Washington

SPECIAL CORRESPONDENCE

A considerable number of additional briefs relating to duties on iron and steel and products thereof have been filed during the past week with the House Ways and Means committee.

PIG IRON

Walter Wood for R. D. Wood & Co., Philadelphia, Penn., presents argument showing that \$3 per ton duty above the tariff on pig iron is sufficient protection for the cast-iron pipe business but that a reduction to less than \$2 per ton would be unwise. He further asserts that any considerable reduction in the cost of pig iron must come from the lowering of the price of Lake ores and urges that a thorough scheme of drawbacks will tend to bring into the United States a large amount of trade which it could not otherwise obtain. E. C. Felton, President Pennsylvania Steel Company, submits detailed estimates of steel costs and urges that the present rate on steel rails is none too high for the protection of the seaboard manufacturer. A. S. Patullo, secretary of the Oregon Iron and Steel Company, Portland, Oregon, advocates a reduction of the duty on pig iron. Leonard Packitt, Catasauqua, Penn., rebuts the arguments of Colne & Co., New York, against duties on silicon iron. He maintains that there is an abundance of "low phosphorus pig iron"—an identical product. Nelson Lyon, Tarrytown, N. Y., submits an elaborate supplemental argument in favor of free pig iron and free raw material in the coarser products of iron and wire, and detailed data on cost of production. John O. Pew, Vice-President the Youngstown, Iron and Steel Roofing Company, Youngstown, O., suggests a moderate reduction in all the iron schedules and urges the substitution of specific for ad valorem duties in Section 135. R. M. Boutwell, Treasurer Portland Iron and Steel Company, Portland, Me., requests the placing of scrap iron on the free list. Chas. Eugene Clark, Covington, Ky., an iron-founder, asks adequate protection for the smaller producer on the ground that he works at a disadvantage. Hon. Chas. Dick has filed a letter from Edwin G. Hough, Secretary of the Chamber of Commerce, Mansfield, O., in which an advance of the duty on iron shot, steel shot, grit and other iron abrasives from 45 to 75 per cent. is urged. W. F. Boardman, treasurer the Calais Shot Works, Calais, Maine, requests a duty of 1c. per pound on chilled shot of all sizes. W. H. Bowker, Boston, Mass., asks to have sulphate of ammonia and basic slag placed on the free list.

The Bessie Ferrosilicon Company, New Straitsville, O., asks that proper protection be granted to ferrosilicon by removing it entirely from the class of pig iron and putting it with such other ferro-alloys

as are made by both the blast furnace and the electric processes. Ferrosilicon whether produced in the electric furnace or by chemical process or otherwise should have a duty of 37½ per cent. on the foreign valuation. W. S. Puling, treasurer the Northern Iron Company, Philadelphia, files charges that the statements of Colne & Co., New York City, relative to silicon iron "are untrue" and urges that there be no tariff discrimination against silicon iron.

LEAD AND ZINC ORES

Marshall J. Smith, Georgetown, Colo., has filed supplemental evidence regarding the need of an adequate duty on lead. C. F. Kendall, manager of the Pay Rock mines, Silver Plume, Colo., furnishes statistics on mining costs pointing to the need of a tariff on lead. Silas Frank, Creede, Colo., urges the retention of the present duties on lead. Frederick Burdidge, representing the lead producers and miners of Idaho, asks the retention of the present duties on lead ore and bullion and supports his argument by citing data from "Lead and Zinc in the United States," by W. R. Ingalls, and from the *ENGINEERING AND MINING JOURNAL*. A body of citizens of the Cœur d'Alene district urges that the present duty on lead bullion and lead ores be not decreased. Thomas L. Wood, Denver, Colo., has filed a lead-ore settlement sheet showing the proceeds of a carload of concentrates and requests the maintenance of the present tariff on lead.

In a supplementary letter S. S. Palmer, president of the New Jersey Zinc Company, rebuts the arguments of the Joplin interests in behalf of a protective duty on zinc. Charles H. Morris, manager of the Altura Mining and Milling Company, and others, Denver, Colo., protests against any reduction of the tariff on lead and demands duties on zinc. James E. Pope, Jersey City, files a denial of statements made by Edward Brush, of the American Smelting and Refining Company, as to the production and marketing of lead. J. W. Marsh, Pittsburg, Penn., general manager of the Standard Underground Cable Company, urges reduction of the duty on lead ores to 0.75c. per pound and on refined lead to 1.125c. per lb. John B. Winfield, Pueblo, Colo., complains of the difference between Canadian and American prices on white lead. The Hanna Paint Manufacturing Company, Columbus, O., complains of the duty on dry white lead and resulting monopoly.

Axel O. Ihlseng, general manager of the Oronogo Circle Mining Company, Joplin, Mo., submits a lengthy analysis of zinc-ore costs in support of his demand for a duty of 1.5c. per lb. on the zinc contents of imported ores. A. B. Cockerill, Nevada, Mo., modifies his statement about Mr. Ihlseng's relation to foreign zinc interests. The H. H. Franklin Manufacturing Company, Syracuse, N. Y., submits

additional material in support of its argument for the reduction or total abolition of the duty on aluminum.

MISCELLANEOUS

The Beckton Chemical Company, Philadelphia, Penn., submits a supplemental brief petitioning that the duty on crude manufactured barytes earth suitable for lithopone manufacture be entirely removed, or at least not advanced beyond the present rate. The W. D. Gilman Company, Sweetwater, Penn., corrects some misstatements and asks for a protective duty of \$5 per ton. The Retail Confectioners and Ice Cream Manufacturers Protective Association of New York recommends removal of the duty on rock salt. Hon. Peter A. Porter files a letter from the Rock Glen Salt Company, Rock Glen, N. Y., asking the retention of present duties or increase of 2 or 3c. per 100 lb. on salt above present rates of 8 to 10c. per lb. H. C. Higginson, president of the Higginson Manufacturing Company, Newburg, N. Y., asks retention of the present duty on refined chalk. George W. Grote, importer, New York City, asks that chalk be placed on the free list. Henry Howard, president of the Merrimack Chemical Company, Boston, Mass., submits detailed argument for placing bauxite on the free list. Hugo Reisinger, New York City, urges that the specific duty system as applied to carbons be abandoned and the rate be 20 per cent. ad valorem. H. Y. Seidel, Philadelphia, requests that crucible clay be retained on the free list. A considerable number of manufacturers support this position. The Glidden Varnish Company, Cleveland, O., protests against any increase of duty above the present \$1.50 per ton on asphaltum. The Southern Fullers Earth Company, Warren, Penn., urges the need of increased duties on fullers earth and supports the views of Harry A. Auer, who appeared before the committee.

Charles Weiler, Milwaukee, Wis., urges an increase of duty on gypsum rock from 50c. to \$1 per ton. The Roman Nose Gypsum Company, Bickford, Okla., requests an advance in the duty on gypsum. Frank W. Wilder, for the Southern Gypsum Company, North Halston, Va., urges that reduction of duties to 25c. per ton would be inadvisable. The Warner-Miller Company, New Haven, Conn., advocates abolition of the duty on gypsum. The Virginia Portland Cement Company, Fordwick, Va., urges free admission of gypsum. The same request is made by a large number of dealers in building supplies. The Best Brothers Keen's Cement Company, Medicine Lodge, Kan., urges that the duties on Keene's cement be raised and be equalized with those on the chemicals used in its production. John C. Lehman, for the Kieglass Lehman Company, Chicago, asks that the tariff on pumice be reduced or certainly not advanced.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres. and Treas. ROBERT McKEAN, Sec'y.
505 Pearl St., New York.

London Office: 6 Bouverie Street, London, E. C. 4, Eng.
CABLE ADDRESS "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs. Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale at all newsdealers generally.
Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for December, 1908, was 42,500 copies.

January 2, 1909, 10,000

None sent free regularly, no back numbers. Figures are live, net circulation.

South African Mining Reports and the Life of the Mines

While the reports issued by the South African Mining companies generally supply the stockholders with ample statistics as to the working of the mines, there is one point on which nearly all of them are deficient. Mining and milling costs and bullion recoveries are given with much detail, and no one can reasonably complain that the results of the year's work are not sufficiently explained. The serious omission is that no information is given as to the probable life of the mine. It is true that in a few cases some estimate is given of the probable date of exhaustion of the ore; but this is the case with only a few of the older mines—such as the Crown Reef, the Ferreira and the Robinson—which have had their lives officially determined, so to speak. This omission is especially to be deprecated in a district like the Witwatersrand, where the determination of ore reserves is more easily made than in any other gold-mining district known.

The dividends of the mines may be regarded as terminable annuities, and unless the reports give some indication of the number of claims to be worked and the probable tonnage, the shareholder is very much in the dark as to the present value of his holdings. Of course, no one who understands how much the tonnage available for mining depends on the cost of working can expect more than an approximate estimate; since the cost must fluctuate according to the labor supply and other causes. It is reasonable, however, that shareholders should obtain from their directors and the engineers they employ the best information possible as to the probable life of their property. The claims worked out and the tonnage obtained are known quantities; so also is the area of claims still unworked. It is, therefore, inexcusable that official reports, while giving copious information about past results and current work, should be totally silent as to the future. It is also remarkable that meetings are held in which shareholders ask many questions, but no one calls for information of the kind indicated.

Of course, the available resources of a mine will vary as conditions change; and a reduction in working costs may make valuable ore formerly considered unpayable. Revaluations must be made

from time to time. Moreover, no one can blame engineers for not foreseeing such reductions in cost; or, on the other hand, variations in average ore value, the occurrence of dikes and faults and other factors that may affect the reserves unfavorably. Stockholders have, however, an undoubted right to expect from their engineers and directors a general report on the probabilities, based on conditions existing at the time the report is made; and indicating to the best of their knowledge and experience what may be reasonably expected.

Another phase of the same question relates to the accounts of the companies. In the balance sheets property account remains at the same, or an increased figure year after year, although the value necessarily depreciates with the ore taken out each year. If these property accounts had been debited each year with the ore taken from the mine—as is done by many coal companies in Europe and the United States—either the capital would be reduced to conform to the estimated future profits, or a sinking fund provided for the benefit of stockholders. Either method would provide for the amortization of the capital, and its extinction when the life of the mine was ended.

Ventilation of Mines

Ventilation in metal mines in the United States is a subject that is commonly dismissed from consideration, or rather it seldom enters into consideration at all; at least, not until the air becomes so bad that candles will not burn. Consequently, there is no well developed practice in this important phase of mining. No arguments should be necessary to prove that it is an important phase, because it is axiomatic that the better are the conditions for the men underground, the greater is their efficiency. Nevertheless, operators are frequently blind to such matters that directly affect their own interest, and it is necessary to insure the welfare of their employees by law. So largely has the subject of ventilation been disregarded, there is only one law—that of New York—that in any way prescribes that good ventilation shall be provided, or even refers to it. Fortunately, several of the States require that every mine shall have at least two exits, which in themselves usually effect fairly good ventilation, although not intended specifically for that purpose.

The simplest means for ventilating a mine is the establishment and proper direction of air currents through it. This can usually be effected, when there are two openings to the mine or connection with some other mine, by the exercise of engineering knowledge and the expenditure of nothing but a little thought and the cost of a few doors, brattices, etc. The results of intelligent consideration of the principles governing air currents are strikingly manifest in the mines of Butte, Mont., which through the decomposition of timber and sulphide ore, and the heat generated by pressure in the fissured and fractured ground are as hot as any mines now operated in the United States. Some of the mines at Butte are so hot that an ordinary candle quickly softens in the fingers, and their atmosphere is exceedingly uncomfortable, both because of the heat and the deficiency of oxygen by absence of circulation; other mines near by, while warm, are not uncomfortable to the men, a proper circulation of air through the workings having been established.

A mine having only one opening can, of course, be ventilated only by a mechanical movement of the air, and when the drives attain long distances from the shaft it is necessary to provide air pipes extending nearly to the breasts, and either force in or exhaust air by means of a fan. In some metal mines opened in a flat-lying deposit, where the workings may cover a large area on one level, a simple and effective means for ventilation is to put down one or more 6- to 8-in. holes with an ordinary churn drill and connect them on the surface with a fan which will exhaust air from the mine through the drill holes. Such drill holes are very cheaply put down to depths of several hundred feet.

The subject of ventilation underground is one that should be given a good deal more attention than it gets. It is not right to compel miners to work under conditions which may injuriously affect their health, even if the men themselves be willing to work in such places without complaint. But aside from this moral aspect of the case, it is the common experience that the better are the conditions for work, the more is the work done. Many managers of mills who neglected for years to clean the windows, found to their astonishment that the better light coming from the removal of the dust and dirt increased efficiency to such an extent that

window cleaning proved to be one of the best investments ever made. The provision of good air is also a fine investment.

Secrecy in the Arts

The best explanation and defense of this mistaken policy, as we consider it to be, that we have seen, have been given by Edgar Hall, of Australia, in a communication published in the September bulletin of the American Institute of Mining Engineers, wherein he discusses the paper of Dr. Douglas, presented at the Toronto meeting of the Institute. Dr. Douglas attributed the decline of the copper-smelting industry in Swansea to the secrecy maintained by the concerns there engaged in smelting.

Mr. Hall argues that the decline of copper smelting at Swansea was due to quite different causes and was inevitable. He points out that Swansea never smelted what is now considered low-grade ore, and never could hope to do so, because even with the advantage of cheap ocean-carriage, nothing but rich ores and matte could stand the freight. With the introduction of the bessemer process matte could be more cheaply treated at or near the mines.

The smelting industry at Swansea was essentially conducted on a custom basis. Today the great producers of copper are the mining companies which do their own smelting, and as Mr. Hall remarks, "It matters little who knows what is being done, for those who may copy their methods cannot take the mine, and it is decidedly of advantage to the smelter to know what others are doing, since every improvement adopted is pure gain and an increase in the value of the mine. But to the custom smelter very often the possession of a 'wrinkle' means the difference between profit and loss, and in the case of the Swansea firms, if they showed their methods freely, it meant that they would be promptly deprived of their supply of raw material."

Undoubtedly there is some truth in this argument, but its mistake on the whole lurks in what Mr. Hall himself says, namely that it is of advantage to the smelter to know what others are doing, since every improvement adopted is pure gain. Such advance in knowledge is only to be secured through an exchange of information. We should feel sorry for the metallurgical firm whose chief capital was a

trade secret, always at the risk of betrayal of a venal employee. The concern which has failed to develop an organization and a guiding policy that will permit it to discard its old clothes to less enterprising competitors, from whom nevertheless it may obtain fragments of valuable experience in exchange, is not likely to keep a position near the head of the procession. This, we think, is verified by the often repeated experience, that when after much trouble an opening is finally gained to previously inaccessible works, it turns out that the veil of mystery has concealed defects in practice rather than the perfection supposed.

The Low Price for Silver Affects the Cost of Producing Lead

We are apt to fall into error of speaking of silver as a by-product that will be turned out irrespective of the price in so far as it is derived from lead and copper ores, but whether the silver of such ores be let go scot-free, or the silver be charged with all it realizes in order to make the copper and lead stand at a low cost, or expenses be proportioned among these various metals, is merely a matter of book-keeping. The fact is, of course, that a decline in the value of silver has a highly important effect upon the cost of producing the other metals, particularly important in the case of the lead mines of the Cœur d'Alene.

Thus, it was computed in an article in the JOURNAL of Jan. 4, 1908, that if the price for silver should fall from 68c. per oz. to 50c., the cost per pound of lead to the Federal Mining and Smelting Company would increase approximately 0.67c., while the Bunker Hill & Sullivan company which at 67.5c. per oz. for silver realized for that metal alone an amount much in excess of the total cost of mining and milling, would fall far short of that exceptional and desirable result if the price for silver should be only 50c. per ounce.

However, with silver at a little less than 50c. per oz. the wolf is not howling at the door of these great lead producers, which on the basis of 50c. per oz. can deliver lead in New York at 3@4c. per lb., including all charges for maintenance, amortization, etc., while if those items were neglected for a time as would be done at a pinch, the cost of production would be 0.5c. per lb. less.

Patent Legislation

SPECIAL CORRESPONDENCE

Representative Stephens has introduced in Congress a bill requiring any citizen of a foreign country who may procure a copyright or letters patent from the United States to pay to the United States for such copyright or patent the same amount of fees and to subject himself to the same laws, rules and regulations relating to such patent, its use and control, as the government of such foreign country exacts by its laws and regulations from citizens of the United States. This is the same proposal which was brought up last spring and at that time received considerable attention from the House Committee on Patents. It was then seriously antagonized by the patent attorneys of the United States on the ground that it would require an immense enlargement of the work of the patent office and throw upon our courts the necessity of familiarizing themselves with the patent legislation of many foreign countries, in addition to numerous technical objections to the proposed measure. The same position is now being taken by the patent attorneys and they are expecting to have hearings before the House Committee on Patents probably during January at which the Stephens bill will be considered and there will be general discussion of methods of retaliation against foreign countries which accept legislation aimed at American interests.

The Conservation Commission

SPECIAL CORRESPONDENCE

It has been determined to send to the President the *verbatim* proceedings of the conservation conference as a part of the report of the Conservation Commission. President Roosevelt will then transmit the whole mass of documents to Congress early in January, and this will insure the publication of the whole as a government document. The President will also make recommendations for a permanent body to take charge of the conservation movement, but no legislation is expected at this session.

Mr. Pinchot will shortly appoint the permanent conservation committee (of voluntary type) which was provided for at the recent meeting of the conservation conference. This consists of six members of State conservation commissions and three members of the national body. It is expected that this joint organization will begin operations at once in conjunction with the various State conservation commissions and will aid in formulating uniform legislation to be urged upon the several State legislatures that will be in session this winter.

Chronology of Mining, December 1908

Dec. 2.—American Mining Congress met at Pittsburg, Penn.

Dec. 3.—Experimental station of the U. S. Geological Survey at the Arsenal grounds, Pittsburg, Penn., formally opened by Secretary Garfield. Guanajuato-Jalisco Development Company organized in New York.

Dec. 7.—Congress reassembled.

Dec. 8.—National Conservation Commission made its first report. President Roosevelt and President-elect Taft advocated the issue of bonds to protect the natural resources of the country.

Dec. 10.—President Roosevelt withdrew from entry all public lands containing phosphate rock in Wyoming, Idaho and Utah. Conference of steel manufacturers at New York, but no action as to prices. Violent break in price of Rawhide Coalition stock.

Dec. 11.—Announcement that Phelps, Dodge & Co., Incorporated, capital \$50,000,000, is to take over all the interests of the firm of the same name. The President-elect, William H. Taft, announced that there will be thorough tariff revision. Announced that on Jan. 1, 1909, the railways will raise freight rates an average of 10 per cent. on east-west shipments and 18 per cent. on west-east.

Dec. 15.—Mexican Congress adjourned until April without taking action on new mining regulations. Federal Mining and Smelting Company resumed dividends on common stock.

Dec. 16.—Fire in quarters of the U. S. Geological Survey at Washington destroyed a quantity of field notes and other valuable documents. C. W. Bray, president of the American Sheet and Tin Plate Company, resigned. Edward Brush, treasurer of the American Smelting and Refining Company, declared before the Ways and Means committee that American lead producers need protection against Mexican producers.

Dec. 17.—Announcement that Cole & Ryan will organize new smelting company to compete with American Smelting and Refining Company.

Dec. 18.—Copper producers met at New York to consider revival of statistical association. Giroux smelter at Kimberly, Nev., burned. E. H. Gary, of the U. S. Steel Corporation, before the Ways and Means committee pleaded for the retention of the present tariff on steel products.

Dec. 21.—Andrew Carnegie declared before the Ways and Means committee that the American iron and steel industry no longer needs protection. Incorporation of International Smelting and Refining Company (the Ryan-Cole company), with capital of \$50,000,000, all common stock. Manufacture of steel begun at Gary, Ind.

Dec. 26.—President Roosevelt appointed

commissioners to consult with authorities of Canada and Mexico regarding the conservation of natural resources.

Dec. 28.—Earthquake in southern Italy and Sicily destroyed thousands of lives and millions of property.

December Dividends

The accompanying table shows the dividends paid in December, 1908, by mining and industrial companies in the United States and by some foreign mining companies.

U. S. Mining Companies.	Location.	Amt. per Share.	Amt. Paid.
Acacia.....	Colo.	\$0.01	\$15,000
Am. Smelters, pfd. A.	U. S.	1.50	225,000
Am. Smelters, pfd. B.	U. S.	1.25	375,000
Bunker Hill & Sull.	Ida.	0.25	75,000
Calumet & Arizona.	Ariz.	1.00	200,000
Calumet & Hecla.	Mich.	5.00	500,000
Colorado.....	Utah	0.08	80,000
Doe Run.....	Pa.	1.50	93,750
Federal Sm'ting, pfd.	Ida.	1.75	210,000
Homestake.....	S. Dak.	0.50	109,200
Mary McKinney.....	Colo.	0.02	26,185
Northern Butte.....	Mont.	1.00	400,000
North Star.....	Cal.	0.75	187,500
Old Dominion.....	Ariz.	0.50	146,622
Old Dominion M. & S.	Ariz.	1.00	162,000
Quincy.....	Mich.	1.00	110,000

U. S. Steel, com.	U. S.	0.50	2,541,513
Total.....			\$12,811,061

Foreign Mining Companies.	Location.	Amt. per Share.	Amt. Paid.
Granby.....	B. C.	\$2.00	\$270,000
Kerr Lake.....	Ont.	0.15	90,000
Mines Co. of America.	Mex.	0.02	40,000
N. Y. & Hond. Ros.	C.	0.10	15,000
Silver Queen.....	Ont.	0.03	45,000
Trethewey.....	Ont.	0.10	94,545
Total.....			\$554,545

The lead-smelting works now in operation in Colorado are those of the Ohio & Colorado Smelting Company, at Salida, and the Globe, Pueblo, Arkansas Valley and Durango plants of the American Smelting and Refining Company. The Grant works, at Denver, and the Philadelphia plant, at Pueblo, are permanently abandoned. The chances are also that the Eilers plant, at Pueblo, now idle, will never run again.

The Simmer & Jack Gold Mine in the Transvaal

SPECIAL CORRESPONDENCE

During the year ended June 30, 1908, at this mine 785,310 tons were crushed, yielding gold to the value of £1,267,410, an average of 7.672 dwt. or \$7.75 per ton. The working expenditure was \$3.89 per ton. During the year 4000 Chinese laborers were replaced by negroes, a change which entailed heavy expenditure. The mill consists of 320 stamps and four tube mills, the average duty being 6.969 tons per stamp day.

During the year underground work on night shift was gradually reduced until at the end of June practically the whole mine was operated on day shift only, resulting in general improvement in efficiency.

One notable omission from the report and from the chairman's speech at the annual meeting is any statement regarding the life of the mine. No attempt has been made to indicate the claims exhausted, or what remains. For additions and renewals of machinery and plant a reserve fund is maintained. For the period under review the sum of £52,500 was appropriated for this fund, which stood at £83,630 at the end of the financial year.

The net revenue on working account was £601,067. Two dividends of 7½ and 10 per cent., as well as a bonus of 2½ per cent. were declared, absorbing £600,000 in all.

The following statement shows the working costs per ton since 1905.

Year to June 30:	1905.	1906.	1907.	1908.
Tons milled.....	475,181	624,507	717,524	785,310
	s. d.	s. d.	s. d.	s. d.
Mining, hauling and pumping.....	14 2 759	12 4 147	11 0 527	8 10 774
Transport of quartz, crushing and sorting.....	11 425	10 039	9 634	6 080
Milling and cyanide.....	4 1 106	3 8 592	3 5 625	3 7 948
General expenses, including maintenance.....	1 6 362	1 11 984	1 6 515	1 4 926
Development.....	2 6 000	2 6 000	2 6 000	1 8 918
Total costs.....	23 3 652	20 4 762	19 4 301	16 2 646

Development account is a book entry, calculated from the tonnage developed in the mine divided by the cost. On June 30, 1908, excess development stood in the books at £115,417, against a tonnage of 1,902,000 tons valued at 7.6 dwt. equal to \$0.20 per ton.

Since 1905 the total tons developed have been as follows:

	Tons.	Value.
1905.....	1,216,064	8.44 dwt.
1906.....	1,215,291	8.4 dwt.
1907.....	1,694,000	7.7 dwt.
1908.....	1,902,000	7.6 dwt.

It is usual on the Rand to aim at the extinguishment of development expenditure in the balance sheet by writing off every year to working costs a somewhat larger amount than has actually been spent during the year. Shafts and property, on the other hand are not written down and the expenditure remains the same in the balance sheet from year to year unless additions are made.

Submarine Petroleum

The story of the present article is told in the engraving from a photograph which accompanies it. This shows an oilfield at Summerland, Cal., where petroleum is obtained from submarine wells. So far as we are aware the situation of these wells is unique in the petroleum industry.

SUBMARINE OIL WELLS, SUMMERLAND, CAL.

subscription and solicitation, shall pay into the treasury of the United States a tax of 0.1 per cent. upon the market value not reckoned below par, of the authorized capital stock of such corporations." The Ways and Means Committee has not committed itself thus far to any scheme of revenue enlargement, but the pressure for the McHenry bill or some measure of the same sort is likely to be strong.

Rhodesian Mines

The gold production of Rhodesia in October is reported at 48,847 oz., or 274 oz. more than in September. For the 10 months ended Oct. 31 the total was 503,447 oz. This year nearly all the mines report in fine gold, but last year the statements were made in hullion. By values the gold outputs for the 10 months was \$3,786,515 in 1907 and \$10,278,512 in 1908; an increase this year of \$1,491,997, or 17 per cent.

The production of other metals and minerals in October included 24,615 oz. silver, 9 tons copper, 85 tons lead, 7 tons wolframite, 386 tons chrome ore and 16,312 tons coal.

West African Gold Mines

The West African Chamber of Mines reports gold production in Ashanti and the Gold Coast in November at 24,437 oz., an increase of 650 oz. over October. For the 11 months ended Nov. 31, the total was 260,287 oz. bullion in 1907, and 272,742 oz. in 1908; an increase of 3455 oz. The bullion reported in 1908 was equal to \$5,295,323, or 256,184 oz. fine gold.

Proposed Tax on Mining Stock^s

SPECIAL CORRESPONDENCE

In considering new revenue legislation, the Ways and Means Committee is being urged to investigate the question of a tax on the stocks of corporations engaged in interstate business, and in this connection the McHenry bill introduced May 12, 1908 (H. R. 22,267), as well as other measures aimed at stock speculation, will be pressed upon the committee. The McHenry bill provides "that on and after the approval of this act all corporations engaged in the mining of asphalt, copper, gas, gold, graphite, iron, lead, oil, radium, silver, tin or zinc, or corporations organized for the purpose of mining or producing those minerals and offering stock of such corporations for sale either in commercial exchanges, boards of trade, or by private

New Publications

THE MOUNT FARRELL MINING FIELD. By L. K. Ward. Geological Survey Bulletin No. 3. Pp. 120, illustrated. $5\frac{1}{2} \times 8\frac{1}{2}$ in.; paper. Hobart, Tasmania, 1908: Department of Mines.

BUECHER-VERZEICHNIS DES VEREINS FUER DIE BERGBAUICHEN INTERESSEN IM OBERBERGAMTSBEZIRK DORTMUND ZU ESSEN. Third Edition. Pp. 491. $7\frac{1}{2} \times 10\frac{1}{2}$ in.; cloth. Berlin, 1908: H. S. Hermann.

REPORT OF THE PENNSYLVANIA DEPARTMENT OF MINES, 1907. Part I—Anthracite; Part II—Bituminous. Pp. 603-938, illustrated. $6\frac{1}{2} \times 9\frac{1}{2}$ in.; cloth. Harrisburg, Penn., 1908: Harrisburg Publishing Company.

MARYLAND MINERAL INDUSTRIES, 1896-1907. By William B. Clark and Edward B. Mathews. Vol. VIII, Part II. Pp. 223, illustrated. 7×10 in.; paper. Baltimore, 1908: Maryland Geological and Economic Survey.

INFORME PRELIMINAR SOBRE LA ZONA PETROLIFERA DEL NORTE DEL PERU. By V. F. Marsters. Boletín Del Cuerpo de Ingenieros de Minas del Peru, No. 50. Pp. 150, illustrated. $6\frac{1}{4} \times 9\frac{1}{4}$ in.; paper. Lima, 1907: Ministerio de Fomento.

THE COPPER-MINING INDUSTRY AND THE DISTRIBUTION OF COPPER ORES IN NEW SOUTH WALES. Second Edition. By J. E. Carne. Mineral Resources No. 6. Pp. 425, illustrated. $6\frac{1}{2} \times 9\frac{1}{4}$ in.; board covers. Sydney, 1908: Department of Mines.

PRELIMINARY REPORT ON THE COALINGA OIL DISTRICT, FRESNO AND KINGS COUNTIES, CALIFORNIA. By Ralph Arnold and Robert Anderson. U. S. Geological Survey, Bull. No. 357. Pp. 142, illustrated. $6\frac{1}{2} \times 9$ in.; paper. Washington, 1908: Government Printing Office.

THE KETCHIKAN AND WRANGELL MINING DISTRICTS, ALASKA. By Fred E. Wright and Charles W. Wright. U. S. Geological Survey, Bull. No. 347. Pp. 210, illustrated. $6\frac{1}{2} \times 9$ in.; paper. Washington, 1908: Government Printing Office.

COAL: Part I—Coals of the Monongahela Formation or Upper Productive Coal Measures; Part II—Chemical Analyses and Calorific Tests of the Clarion, Lower Kittanning, Middle Kittanning and Upper Freeport Coals. Geology by J. A. Bownocker; Chemistry by N. W. Lord and E. E. Sommermeier. Pp. 342, illustrated. $6\frac{1}{2} \times 9\frac{1}{2}$ in.; cloth. Columbus, Ohio, 1908: Geological Survey of Ohio.

A TEXT BOOK OF PHYSICS. Edited by A. Wilmer Duff. Pp. 680; illustrated. $5\frac{1}{2} \times 8$ in.; cloth, \$2.75. Philadelphia, 1908: P. Blakiston's Son & Company.

This work is the result of the collaboration of seven distinguished American

physicists, the idea being that its important subject would best be treated by specialists. Such an undertaking is apt to be characterized by lack of coordination. In the present case the editor deserves congratulation upon his success in welding the contributions into a uniform treatise. Mechanics and properties of matter are treated by Professor Duff; heat by Professor Guthe; wave motion and sound by Professor Hallock; light by Professor Lewis; electricity and magnetism by Professor Goodspeed; electromagnetic induction by Professor Carman; and conduction of electricity through gases and radioactivity by Professor McClung. The work is in all respects up-to-date and is a valuable contribution to knowledge. It appears to us as likely to meet the needs of students for a modern textbook of this science.

ROCKS AND ROCK MINERALS. By Louis V. Pirsson. Pp. 414; illustrated. $5\frac{1}{2} \times 7\frac{1}{2}$ in.; cloth, \$2.50. New York, 1908: John Wiley & Sons, London, Chapman & Hall, Ltd.

Contents: Scope of petrology; historical; methods of study. Chemical character of the earth's crust and its component minerals. Important properties of minerals. Description of the rock-making minerals. Determination of the rock-making minerals. General petrology of igneous rocks. Description of igneous rocks. Origin and classification of stratified rocks. Description of stratified rocks. Origin, general characters and classification of the metamorphic rocks. Description of metamorphic rocks. The determination of rocks.

This is an uncommonly good book upon a subject that is troublesome to all but the trained petrologists. It will be particularly useful to geologists and mining engineers because of the table for determining rocks like those for determining minerals by their physical properties.

STEAM POWER PLANT ENGINEERING. By G. F. Gebhardt. Pp. 816; illustrated. $6\frac{1}{2} \times 9\frac{1}{4}$ in.; cloth, \$6. New York, 1908: John Wiley & Sons; London, Chapman & Hall, Ltd.

Contents: Elementary steam power plants. Fuels and combustion. Boilers. Smoke prevention, furnaces and stokers. Superheated steam and superheaters. Coal- and ash-handling apparatus. Chimneys. Mechanical draft. Steam engines. Steam turbines. Condensers. Feed-water purifiers and heaters. Pumps. Separators, traps and drains. Piping and pipe fittings. Lubricants and lubrication. Finance and economics; cost of power. Testing and measuring instruments. Typical specifications. Typical plants. Tables. Bibliography.

The author of this work is professor of mechanical engineering at the Armour School of Technology. It is intended to be primarily a textbook for engineering students, but it is hoped that it will also

be of interest to practicing engineers. It will be. It is indeed a monumental work, which, while covering much of the same ground as Professor Hutton's classic, looks at its subject from a different viewpoint and contributes important supplemental information.

ELECTRO-METALLURGY. By John B. C. Kershaw. Pp. 303, illustrated. $5\frac{1}{2} \times 8\frac{1}{2}$ in.; cloth, \$2. New York, 1908: D. Van Nostrand Company.

This book is interesting in many respects and a good deal of valuable information may be obtained from it if the reader be sufficiently well informed to sift out and reject the frequent inaccuracies and belated data. The plan of the author has been too ambitious. In writing a treatise on electrometallurgy in 297 pages and going into such subjects as glass, graphite, carbon bisulphide and others that do not belong to electrometallurgy, there remains obviously an inadequate space for the important subjects like aluminum, copper and iron.

The author's treatment is purely descriptive; in no respect critical and analytical. For example, in his chapter on zinc he describes certain of the hydro-electrometallurgical processes, but fails to indicate the causes of the failure of most of these, or point out that they are bound to fail unless the anode reaction can be utilized, as in the Hoepfner process, or extraordinarily cheap power be available. His explanation of the failure of the Ashcroft process at Cockle Creek is woefully inadequate. Similarly in the matter of the electrothermic processes the data cited are visionary and the great metallurgical difficulty experienced by De Laval, who is the only one that has commercially produced zinc in this way, is not even mentioned.

The chapters on copper and lead are hopelessly out of date. Merely as illustrations we may mention that the Anaconda refinery has not been operated for years, while in the case of the Betts lead process the most important works employing it, namely, Grasselli, is not referred to. Indeed, Mr. Kershaw's book has the appearance of preparation several years ago and publication after a long delay without any serious attempt at revision. In the meanwhile progress has been rapid. The book is obviously to a large extent a compilation, but the best authorities have not always been consulted although their works have been available. The estimate that it costs 25c. per lb. to produce aluminum will provoke a smile in these days when it is selling for $13\frac{1}{4}$ c. If such errors were few and obviously mere slips on the part of the author, who cannot be expected to show omniscience, we should not so strongly call attention to them, but unfortunately the book is permeated with them, which deprives it of value except to the discriminating reader, and he is likely to decline to do the sifting that the author ought to have done.

Personals

Mining and metallurgical engineers are invited to keep THE ENGINEERING AND MINING JOURNAL informed of their movements and appointments.

S. F. Shaw is in Tombstone, Arizona.

W. de L. Benedict is in San Francisco.

Henry S. Washington has returned from Brazil.

Paul R. Hare is managing a dredge at Pierce, Idaho.

Walter H. Bunce has gone to Argentina on professional business.

Rene Hazard is operating a hydraulic mine near Medellin, Colombia.

Lester W. Strauss has been examining coal and copper in southeastern Peru.

E. B. Kimball and Louis Decoto are investigating mines near Zaragoza, Colombia.

Raymond Linton is examining quartz and placer mines near Tuquerres, Colombia.

F. J. Siebel is superintendent of the Burlington mine at Sutter Creek, Amador county, California.

F. T. Havard has opened an office as consulting mining and metallurgical engineer at Helena, Montana.

Hugh Rose, superintendent of the Guanajuato Development Company, Guanajuato, Mexico, is visiting New York.

James Gallagher has resigned his position as manager of the Joplin Mining Exchange at Joplin, Mo., to go into private business.

P. L. Williams, Jr., general superintendent of the Daly-West mine at Park City, Utah, has returned to Utah from a business trip to Chicago.

Lafayette Hanchett, general manager of the Newhouse interests in Utah, has returned to Salt Lake City from a business trip to New York and Boston.

John V. N. Dorr, of Pluma, S. D., is acting as consulting engineer for the Golden Reward Mining Company in the installation of a Moore process plant.

Joseph Wharton, the veteran ironmaster and blast-furnace operator, has presented a tract of 25 acres at Fern Rock to the city of Philadelphia, to be used as a public park.

H. C. Cutler, consulting engineer for Nixon & Wingfield, has returned to Goldfield, Nev., after three weeks spent in examining mining claims in Sonora, Mexico.

W. F. Battersby, of the Kingston School of Mines, has been awarded the prize of \$500 offered by J. B. Tyrrell, mining engineer, Toronto, for the best collection of Ontario minerals made during the past season.

F. W. Ridley has been appointed superintendent of the Allouez and Centennial mines in the Lake Superior copper district. Mr. Ridley has had charge of the

Superior, LaSalle and Gratiot properties since they came under the management of the Calumet & Hecla.

Dr. George E. Ladd has been appointed president of the new Oklahoma School of Mines, at Wilburton, Okla., and will take charge soon of the organization. Dr. Ladd was formerly in charge of the Missouri School of Mines at Rolla, but for some years past has been engaged in zinc mining in the Joplin district.

John Laing, of Sharon, Kanawha county, president of the Wyatt Coal Company, and for several years interested in the Rush Run operation on New river, has been appointed chief mine inspector of West Virginia in place of James W. Paul, who resigned some time ago to accept a position with the United States Geological Survey. Mr. Laing began life as a miner and gradually worked his way up until he became an operator on a considerable scale.

Obituary

Henry. Wallace Caldwell, president of the H. W. Caldwell & Son Company, of Chicago, and founder of the business, died Dec. 22, at Redlands, California.

Societies and Technical Schools

American Institute of Mining Engineers—The following committee on the Conservation of Natural Resources has been appointed to cooperate with the National Commission; John Hays Hammond, chairman; T. H. Watkins; Gardner F. Williams; James Douglas; Walter Reuten Ingalls; Charles Kirchhoff; Theodore Dwight; Joseph Struthers.

Colorado School of Mines—President Victor C. Alderson, of this school at Golden, Colo., announces that a number of courses will be added, beginning with the college year 1908-1909. They are intended for technical graduates who wish to specialize along various lines. The new courses include coal mining; coal testing; mine-plant testing; advanced general metallurgy; metallography; gas-engine design; kinematical drawing of mining machinery; advanced mine and mill design; advanced hydraulic design; ceramic geology; cements and clays; chemistry of the rare metals; electrochemical analysis and experiments; radio-activity and spectroscopy; practical astronomy; precise surveying and geodesy; microscopic petrography; electricity applied to mining.

Imperial Pei-Yang University—The professor in charge, N. F. Drake, has issued an excellent pamphlet of instructions for the use of the students in the mining school of this institution at Pei-Yang, China, who are engaged in field work. The course of study required comprises careful and detailed observations, note-taking and sketching of metallurgical and mining

methods and plant and geological features, such as will lead to a general practical knowledge of the subject. It is intended that the work as outlined shall be divided among these subjects as local conditions and opportunity may offer. The list of subjects covered is comprehensive, and is divided as follows: 1. Metallurgy, including: (a) Iron and steel plants; (b) Coal washing and coking plants; (c) Lead and copper smelters; (d) Cyanide plants; (e) Ore-dressing plants. 2. Mining, including: (a) Drilling and blasting; (b) Stopping ore and breaking coal; (c) Development and working the mine; (d) Handling and transporting ore; (e) Timbering; (f) Shaft sinking; (g) Drainage; (h) Ventilation; (i) Lighting; (j) Surface plant; (k) Handling men; (l) Water supply; (m) Organization; (n) Supplies and material. 3. Geology includes: (a) Local geology and topography; (b) Ore deposits; (c) Coal beds; (d) Miscellaneous economic products.

American Chemical Society—The 39th general meeting was held in Baltimore, Dec. 20-Jan. 1, in connection with that of Section C of the American Association for the Advancement of Science. The meeting was divided for the reading of papers and discussion into nine sections. Among the papers read in the division of Industrial Chemists and Chemical Engineers were the following:

1. Walter O. Snelling. The Munroe Crucible.
2. Percy H. Walker and H. A. Whitman. Rapid Analysis of Babbitt Metal.
4. Allerton S. Cushman. Acceleration Tests of the Resistance to Corrosion of Iron and Steel.
5. David T. Day. The Changes in Crude Petroleum Effected by Diffusion through Clay.
6. George Auchy. Further Remarks on Vanadium and its Estimation.
7. Paul N. Clancy. Iron, from a Chemical and Commercial Standpoint.
9. W. H. Walker. Principles Underlying Efficient Grinding and Separating.
10. H. J. Skinner. The Purchase of Material on Specification.
14. E. G. Bailey. Accuracy in Sampling Coal.
20. Charles E. Munroe. The Commercial Manufacture of Amorphous Calcium Phosphide.
21. Charles E. Munroe. The Distribution of Nitrate of Soda in the United States.

In the Fertilizer Chemistry division papers were presented by George D. Leavens on Determining the Availability of Phosphoric Acid in Basic Slag; by F. P. Veitch on Determination of Iron and Aluminum in Phosphate Rock; by Lucius P. Brown on the Chemistry and Geology of the Inland Phosphates of the United States.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at
San Francisco, Butte, Goldfield, Nev., and London, England

REVIEWS OF IMPORTANT EVENTS

San Francisco

Dec. 24.—The counties around the bay of San Francisco have been experiencing unusually cold weather the past week and a thermometer at 36 deg. has been giving many a surprise. In the mountain and foothill counties there have been heavy snows, greatly to the delight of the mining communities, for this insures a summer water supply. Some of the power plants have been frozen up for a time. In the oilfields of Kern and Fresno counties they have had temperatures of 20 and 27 deg., which is most unusual. The miners throughout the State are hoping for more snow and cold weather so that the snow supply may be added to and none now fallen melted. Cold weather has been experienced throughout the State, south as well as north. A few small but unwelcome earthquakes have been experienced in the bay region, just as a reminder that we are still on that "fault line" which slid so badly in 1906.

The Anti-Débris Association at Sacramento is again active in beginning suits against miners who are hydrauliclicking or ground-sluicing. Agents or "spies" of the association have been bringing in reports of operations of the miners. The district attorney of Sacramento has agreed to prosecute the suits instituted, and proceedings have been commenced against 65 miners at Gold Run, Placer county. The suits are to enjoin the miners from depositing débris in the American river and petition for a writ of injunction; this injunction has been issued against all these men. Not only hydraulic miners operating under a federal license issued by the California Débris Commission are involved, but those working with ground sluices. These latter do not come under the provisions of the Caminetti law, but are to be prosecuted under the common law.

Suits are also to be brought in Sutter county against miners along the Bear, Feather and Yuba rivers in three different counties. A large number of gravel mines will be affected by these suits. It has come to such a pass that numerous miners have written to the Anti-Débris Association asking whether they would be allowed to mine by hydraulic process and under what conditions. Yet the Anti-Débris Association has no official standing and is composed merely of private citizens opposed to mining. Meanwhile there is in existence a federal commission appointed by the President of the United States under instructions from Congress,

which is authorized to issue permits to mine by hydraulic process when suitable restraining works are built. The Anti-Débris Association ignores these legal permits or licenses, pays no attention to them, and brings suits where licenses to mine have been issued with all due forms of law. And now the miners go to the association instead of to the commission to find whether or not they can mine. The association intends during the winter to carefully control the hydraulic field and see that no new hydraulic mining is commenced.

Several creditors have filed a petition in the U. S. District Court asking that the Northern California Gold Mines Company be adjudged an involuntary bankrupt.

Mining affairs are more than active in certain portions of Inyo county at present. The Monster mine near Big Pine has been sold to Eastern men. L. T. Oddie, of Tonopah, has bonded and leased the Wright lead-silver mine in the White mountains about 12 miles from Big Pine. Ore will be shipped to the new smelter of the Four Metals Company at Keeler. Hagerman & Todd, of Colorado Springs, Colo., are opening a copper claim in the Argus range near Ballarat. In the Argus range a new district is being formed to be known as Custer. Chedago, the Shive Unthank lease, is beginning to pay. This lease is in the Taylor & Cummings property. New silver-lead prospects are being opened in the Modoc group lying north of Cerro Gordo. At Skidoo there is more ore ready than the custom mill can handle.

There is a good deal of activity in Butte county especially on the Magalia ridge. Several large companies are at work in the gravel channels of that vicinity. The Mesilla Gravel Company is about starting in on its property on the same channel where the Cape Horn company is operating. The Cohen property on the same channel is being exploited.

The old Hewel ranch on the upper Stanislaus river, eight miles above Oakdale, opposite and above the Orange Blossom colony, has been sold to H. C. Norris and Chas. A. Marsh, of Los Angeles and John Horning, of Chicago. The property consists of 1600 acres, of which about 400 acres are supposed to carry auriferous gravel in paying quantities if mined by dredges. The ground has been partially tested and the purchasers intend to install a gold dredge.

The Payne ground near Trinity Center in Trinity county is being prospected by

Oroville men with a view to purchase should the gravel be rich enough to pay for dredging.

W. S. Kendall has brought suit to enjoin the El Dorado Dredging Company, of Folsom from asserting any right or title to certain lands owned by him. He says he entered into an agreement with the company giving it the right to dredge the Ingleside fruit farm and the Home farm for gold. He alleges that the company did not begin work according to the agreement and because of this failure he says the agreement became null and void. The El Dorado company recently sold its entire interest to the new Consolidated Company.

Goldfield, Nevada

Dec. 22.—Figures from the office of the State bullion-tax collector show that during the first 9 months of 1908 Esmeralda county produced \$3,886,257. Of this total the Florence Goldfield produced \$2,132,225; the Goldfield Consolidated produced only sufficient ore to run the Combination mill, for no general stoping will be done until the new 600-ton mill is running. The Florence Goldfield has produced no ore on company account during this time; all its production came from leases.

The oil excitement between Goldfield and Blair continues, although only one company is doing any extensive drilling. It claims to have obtained a small quantity of oil and feels confident that the hole is about to enter the oil-bearing stratum. An accident to the drilling outfit will delay work for about two weeks.

The first ore to be stored in bank vaults in Goldfield in several months is that being mined by Mitchell & Fairfield from the Daisy-Florence lease. Some of this ore is valued at \$5 per pound. Only ore that shows ribbons of free gold is being taken to the bank, although the ore as it is broken averages between \$200 and \$500 per ton. Another rich strike in the company workings of the Florence centered public attention again on this property, which since its discovery in 1904 has produced nearly five and a half million dollars, all but about half a million of which has come from leases.

Mina has been visited by a fire which swept the central portion of the town. The damage was about \$100,000.

The Great Western mine at Hornsilver, which, from a rich silver mine, is developing into a rich gold mine, is being exam-

ined by engineers hired by Baltimore and Kansas City men.

The Clermont shaft of the Goldfield Consolidated company has cut the Mohawk vein at a vertical depth of 856 ft. This is at a depth of 1250 ft. on the plane of the vein which dips 35 deg. The ore along the hanging wall is reported to assay \$22 per ton.

Butte

Dec. 24—E. P. Matthewson, general manager, and C. H. Repath, construction engineer, of the Washoe smelter at Anaconda, have returned from a trip to Tooele, Utah, where they were engaged in laying the plans for the new Cole-Ryan smelter. They state that arrangements have been made for laying out the site of the smelter and for erecting temporary quarters for those carrying on the work.

Announcements of the annual meeting of the Montana Society of Engineers have been sent out by Secretary C. H. Moore, of Butte. The society will meet at Great Falls and will be in session Jan. 7, 8 and 9. Nominations for officers for the coming year are as follows: For president, Charles H. Bowman; for vice-president, Frank M. Smith; for second vice-president, F. W. C. Whyte; for secretary and librarian, Clinton H. Moore.

Deputy State Mine Inspector W. B. Orem, in charge of the Butte district, has made his report for the year 1908. The report calls attention to the remarkable increase in the use of electric power for hoisting and pumping purposes in the Butte mines within the past year, and the consequent betterment of ventilation, especially in the deeper mines. It is stated that the substitution of electric power for steam has in several instances reduced the temperature in the mines as much as 20 deg. F. Among the 10,000 men working during the past year but to have met death by accident, a decrease of almost 50 per cent. from 1907.

The case of the United States against the Northern Pacific Railway, the Northwestern Improvement Company and the Rocky Fork Coal Company, will be heard in the Federal Court at Helena on Jan. 11. The action is brought by the Government for the purpose of setting aside the title of the defendants to certain coal lands in Carbon county, Mont., valued at \$100,000. In the complaint it is alleged that the lands were obtained from the Government by fraud.

London

Dec. 21—In the Journal of Sept. 26 the litigation between the British Ore Concentration Syndicate, Ltd., and A. Stanley Elmore and the Minerals Separation, Ltd.,

was referred to, and your readers were informed that the Ore Concentration Company failed to prove that the Mineral Separation process was an infringement of its patent, but that the case would be appealed in a higher court. The judgment of the Court of Appeal has now been given and is in favor of Elmore and the British Ore Concentration Syndicate. There were two patents involved in this action, that granted to Francis Edward Elmore, No. 21948 of 1898, in which concentration of metalliferous particles in ores is to be effected by the use of thick oil; and second, that granted to Alexander Stanley Elmore, No. 6519 of 1901, in which the use of all oils thick and thin, though preferably thick, is referred to, as well as the advantage of using a small quantity of acid. The 1901 patent is a much wider specification than that of 1898. Both the lower and upper courts decided that the Elmore patent of 1898 was valid, but the process of the Minerals Separation company did not infringe it. The decision turned principally on the point that the Elmore process was limited to the use of heavy oil, while the Minerals Separation company used a thin oil.

As regards Elmore's patent of 1901 the lower court decided that it was not valid and consequently the question whether the Minerals Separation process was an infringement or not, did not arise. But in the Court of Appeal, the judgment was that Elmore's process of 1901 was valid and that the Minerals Separation process was an infringement. To upset the validity of the 1901 patent, the defendants brought forward the specification of Everson's American patent of 1886, and the specification of an English patent granted to Joseph William Sutton in 1892. The court decided that there was nothing in the Sutton specification which was remotely relevant. As regards Everson's specification, the court decided that it was entirely different from the Elmore process. In the Everson process the ore and oil, with or without an acid or neutral salt, are mixed into a stiff mass and the gangue is then washed out. In Elmore's patent there must be a flowing pulp of ore and water. This feature is vital. The result of the appeal is therefore that the Elmore patent of 1901 is held valid and that the Minerals Separation process, which employs thin oils and acid and is considered to be substantially the same process as Elmore's, is held to be an infringement.

West African Mines—Much interest has been aroused in the announcement made during the week that the Consolidated Goldfields of South Africa, Ltd., had decided to invest a large sum of money in West Africa. Arrangements have been made for providing the Efuenta (Wassau) Mines, Ltd., the Fanti Mines, Ltd., and the Wassau West Amalgamated mines with working capital. These mines are situated in the Tarkwa

district and own a large stretch of outcrop of the banket reef, and are neighbors of the Tarkwa, Abosso and Abontiakoon Block 1 mines, which are producing gold on a large scale. A reduction in working costs has taken place in the last year or two and further reductions are anticipated.

It is no doubt on the strength of the improved position of the existing mines that the Consolidated Goldfields are taking a large interest in properties as yet only developed on a small scale. The goldfield has up to the present given disappointing results. There is a large output of gold, amounting last year to over £1,000,000; but owing to the heavy expenditure, caused by the unhealthiness of the climate, the profits are small. The goldfield has no doubt great possibilities and if the expectations of reduced costs, which some engineers claim can be made, are realized, more prosperous times for shareholders in Gold Coast mines may be seen.

Tanganyika Concessions—The report of the Tanganyika Concessions, Ltd., for the year ending June 30, 1908, has been issued. A provisional arrangement has been made for the construction of a railway to connect the Rhodesian railway system, which has now reached Broken Hill, with the Star of the Congo in the Congo State. Ultimately the railway is to be continued to the Ruwe mine and linked up with the Benguella Railway, thus affording access to the west coast.

For the near future the outlet for the copper of the Congo will be through Rhodesia at Beira on the east coast. At the Kansanshi mine in northwestern Rhodesia a furnace is smelting about 500 tons of ore a month, yielding an output of about 90 tons of copper in the form of ingots. It is proposed to send out a larger furnace to treat at least 1250 tons of ore per month, which will give an output of from 200 to 250 tons of copper. Allan Gibb, the engineer of the company, writes that under present conditions the cost of producing copper is £16 per ton. With the proposed new plant, the cost of producing copper will be £12 10s. per ton. Smelting commenced in April and up to September 500 tons of copper have been produced.

At the Kambove and Star of the Congo mines, situated in Belgian territory, large quantities of copper ore are said to be available for mining, and the installation of a smelting plant is being considered. Transport is at present the main difficulty.

A consignment of 50 tons of copper was brought by wagon from Katanga to Benguella, while transport between Kansanshi and the end of the railroad at Broken Hill is being carried out by traction engines.

The Tanganyika company has purchased a coal property, plans of which are attached to the report, from the Zambesia Exploring Company.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Arizona

GILA COUNTY

Miami—Drifts on the 570-ft. level have again run into high-grade ore. This accounts for the recent rise in the stock.

Old Dominion—The plant made a record production of copper during December. The full battery of six furnaces has been in operation part of the time, turning out copper at the rate of about 4,000,000 lb. per month. One of these furnaces is shut down at present undergoing repairs, but it will be put in operation again in a short time. It is believed that the Old Dominion will produce for the year 1908 not less than 38,000,000 lb. of blister copper.

Eureka—H. B. Howland and Hoyal A. Smith and associates have taken over this group of claims owned by D. D. Sullivan, of Globe, J. Warren Young, of Chihuahua, and Frank Tabinski and Patrick D. Sullivan, of Calumet, Mich. The property is seven miles southwest of Globe, and consists of 10 claims. The consideration is \$300,000.

California

AMADOR COUNTY

Amador Queen—George Hambrick and associate leasers have shipped a quantity of rich ore to the smelter and have had their leases renewed for two years.

Bunker Hill—This mine has just made its best record for a month—\$23,000 for November. An extra dividend has been declared for Christmas. E. H. Harrington is superintendent.

Original Amador—This mine, which has been idle several years, is being opened by a new company.

Treasure—In this mine, Amador City, prospecting operations have reached a depth of 400 ft. under superintendency of L. R. Poundstone. Good milling ore has been found.

BUTTE COUNTY

Mesilla Valley Gold Gravel Mining Company—This new company is to mine on an extensive scale near Pentz on the Magalia ridge. E. C. Wilson, of Pentz, and A. M. Wilson, of Cherokee, are among the incorporators. This was formerly a hydraulic mine, but it is now to be drifted.

CALAVERAS COUNTY

Benson—This quartz mine, near Altaville, after a year's idleness, is being reopened. The property has a 20-stamp mill and 20-drill compressor plant driven by electric power. George Walker is superintendent.

Red Gold—J. Campbell is arranging to reopen this quartz mine at Angels.

EL DORADO COUNTY

California-Manhattan—In this mine, near Nashville, an 8-ft. ledge has been crosscut which carries about \$14 per ton. A mill is to be put up on the property.

Independent—Albert Shafsky, of Placerville and Seymour Hill, of El Dorado, in reopening an old prospect near El Dorado, have taken out about \$30,000 within 20 ft. of the surface. The vein found is about 8 in. wide.

HUMBOLDT COUNTY

Orleans—At this place, on the Klamath river, Luther Heacock recently made a strike on Ten Eyck creek in a rich seam of rock. At the Harvey & Pierpoint mine, owned by Mr. Head, a mill is now running. The Doney & Little claims are being developed and the mill will soon be started on ore.

INYO COUNTY

Custer—This is the new camp in the Argus range about 14 miles off the line of the new railroad the Southern Pacific is building to Keeler. The Custer Mining Company has 50 claims in the district, and has already built a five-stamp mill.

NEVADA COUNTY

Lion and Torpie & Schroder—H. M. Black, superintendent of the Ironclad mine, has bonded these two claims in Rough and Ready district and will shortly commence work upon them.

Rose Hill—This Grass Valley company is about to install machinery so as to sink 500 ft. on the ledge.

Yuba—At this mine, C. A. Marriner, manager, the 30-stamp mill has been started up.

PLACER COUNTY

Cash Rock Dredge—This dredge has quit work for the season and the divers have been discharged. Many large boulders interfered with the work this year, and they had to be drilled and blasted under water.

Colorado

OURAY COUNTY

Camp Bird, Ltd.—A report from the London office shows that for the quarter ended Oct. 31 last the mill crushed 20,791 tons dry ore. Receipts from bullion sold were \$402,330; concentrates, \$75,269; total, \$477,599. Working expenses of all kinds were \$143,139; construction accounts, \$9306; London office, \$4500; total, \$156,945, leaving a balance of \$320,654. A dividend of 1s. per share, requiring \$41,000, was paid Nov. 7. In the mine development work was 1058 ft.; cubic feet stoped, 158,000. On Oct. 31, the total dry ore broken in the stopes amounted to 79,636 tons.

The report further says: "The general manager, W. J. Cox, at the suggestion of the consulting engineer, John Hays Hammond, came to London to lay before the directors their recommendations regarding the future developments at the mine, advised by the geologist, J. E. Spurr, in his reports on the property. The directors, after careful consideration, have decided to adopt these recommendations, among which, in brief, are: (1) To discontinue developments in depth, and exploit the upper horizon of the Camp Bird vein and other veins on the company's property. (2) To drive a crosscut to the Coronado and other veins from the second level, and drift extensively in both directions on the veins when cut. With this end in view, the manager, on behalf of the company, has acquired the Trilby, Tip-top, Minnie Lee, and claims Nos. 1, 2, 3, 4, and 5, which the directors are pleased to report he has been able to do on very favorable terms."

LAKE COUNTY

Chrysolite—In this mine, Fryer hill, P. McGreevy and associates are leasing several blocks of ground at the 200-ft. level and for some time past have been shipping a good grade of iron, at the same time carrying on development work. In one drift where this work was being done at 180 ft. from the shaft a vein of ore 12 ft. wide was caught and driven for several feet when a streak was noticed in the center of the orebody, samples were taken from it giving high returns in silver and 67 per cent. lead. The find was made in virgin territory, and will no doubt prove to be an extension of one of the shoots that made the mine famous in early days.

Cleveland—In this mine, South Evans

gulch, preparations are now being made to start sinking the shaft another 100 ft., and work will be commenced by the first week in January. When the contract is completed and the drifts to the north and south opened it will give the company sufficient ground to work for another two years. The fissure vein continues to produce some rich gold ore, and it is expected with depth that the ore will carry greater values.

Favorite—In this mine, South Evans gulch, for several days a small streak of ore has been followed at the 175-ft. level.

Michigan COPPER

Odyssey—No. 2 shaft of this company has reached the third, or 650-ft. level, and a station is being cut preparatory to cross-cutting to intercept the lode. No. 1 shaft is down about 630 ft. and will probably strike the lode about the same time as No. 2 owing to the close proximity of the lode to this shaft.

Centennial—No. 1 shaft of this property is sinking below the 34th level and No. 2 shaft is at the 32d. These shafts start 90 ft. apart at the surface and diverge, and at this depth they are about 600 ft. apart. Drifting to the north of No. 1 is opening up some good-looking ground.

Allouez—At No. 1 shaft sinking has been discontinued just above the 13th level. No. 2 shaft is now at the 12th level, and the pitch of the shaft is being changed to conform with the dip of the formation. It is calculated that this shaft will cut the lode in about a month. Drifts from the lower levels of No. 1 shaft to the south are opening a good grade of rock.

North Lake—This company has not yet reached the ledge with the sand pipes that it is sinking preparatory to diamond drilling; the overburden at these points is between 400 and 500 ft. thick.

Lake—The new hoisting engine at this property has gone into commission and a four-ton skip is now doing duty in the shaft. Sinking continues and the shaft is nearing the third level, with the same rich ground in evidence throughout. The new air compressors will, in all probability be ready to do duty as soon as this level is reached and additional drills are added.

Elm River—This company has begun crosscutting toward the east from the bottom of its exploratory shaft, a distance of 200 ft. from surface. The crosscut is being driven to intercept the various formations believed to traverse the tract and can be extended a distance of about 2000 ft. or to the eastern boundary of the property.

Calumet & Hecla—This company has begun the erection of its electrically driven subshaft hoist. This hoist will be placed at the end of a drift from the 57th level of No. 5 shaft and the subshaft will com-

mand the ground tributary to the five forties north of the Tamarack, Jr., property. The rock will be hoisted to surface through the Red Jacket shaft.

Missouri

ZINC-LEAD DISTRICT

Church-Mitchell—This mine at Duenweg has resumed operations after being shut down for five months.

Isabel—This mine at Alba lost its mill and most of the machinery by a cave of the workings.

Kalitan—This company has put drill holes to one more novel use in sending timber into the mine through them.

Lehigh Circle—This company has been incorporated with a capital stock of \$50,000. The stockholders are F. A. Brown, of Duluth, Minn., and Squires & Strohm, of Joplin. C. F. Strohm, of Joplin, is secretary. The company has a lease on 206 acres of land in Center Creek valley, near Lehigh, on a 10-per cent. royalty.

Mattes Brothers—This company has nearly completed moving the 400-ton San Gabriel mill from Duenweg to its land southwest of Joplin.

Oronogo Circle—This company at Oronogo has installed a dredge boat, equipped with a large centrifugal pump and driven by electric power, to clean out the settling ponds and return the sludge to the mill.

Pinnacle—This company, of Joplin, has leased the Hill Top tract at Oronogo from the Granby company and has let a contract for the erection of a 350-ton mill. J. H. Tonkin, of Joplin, is manager.

Sturgis Mine—This property, adjoining the K. C. Bradford lease at Carterville, has been sold to C. C. Playter, of the United Zinc Company; M. A. Shepard, of Chicago, and G. M. Burke, of the Bull Frog company, Joplin.

Montana

BUTTE DISTRICT

North Butte Extension—John A. Ryan has returned from New York, where he has been in conference with the directors of the new North Butte Extension Development Company. Mr. Ryan now represents both the old and the new company and will have entire charge of operations at the company's properties in Butte. He states that the work of unwatering the shaft will be begun by the first of the year.

JEFFERSON COUNTY

Corbin Copper Company—This company has recently been formed under the laws of Michigan for the purpose of operating a group of 28 claims in the Corbin district. The company has 150,000 shares of capital stock. Of this amount 90,000 were given in exchange for the property and 60,000 placed in the treasury; 25,000

shares of the treasury stock will be sold at \$5 per share for development purposes. The property has been developed by tunnels having an aggregate length of 1000 ft. The directors are Stephen R. Dow, Richard M. Edwards, George E. Learnard and N. W. Jordan.

Kelly Smelting and Refining Company—The Alta group, consisting of seven patented claims, will be actively worked by this company which has recently secured control of the claims. The Kelly company has been operating at the Kelly camp in New Mexico, where it owns a number of mines and a smelter. It is stated that two 3-compartment shafts will be sunk and a concentrator erected on the property. The company's directors are L. O. Hedden, S. W. Traylor, Warren Curtis, Marcus Hewett and ex-Governor Hauser, of Montana.

FERGUS COUNTY

Half Moon Pass Mining Company—The company has recently been formed to operate a group of six gold claims situated about 30 miles from Judith. Seven men are now employed at the property under the direction of Thomas Stigen. It is proposed to erect a mill next spring.

CARBON COUNTY

Frank L. Clark, Dr. M. Souders and Louis Chapman have sold 480 acres of coal lands situated in the Bear Creek district to Thomas Ryan, representing Nebraska capitalists. Mr. Ryan has been on the property with a corps of engineers for several months making an examination.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Daisy-Florence—This lease on the Florence operated by Mitchell & Fairfield is lacking high-grade ore. The sacked ore is being stored in the vaults of the Registration Trust Company pending shipment.

Atlanta—The Cherokee lease has installed a hoist; sinking will be resumed as soon as financial arrangements now under way are completed.

Consolidated Mill—The mill bins now contain 4000 tons of low-grade ore ready for the initial run of the stamps which is scheduled for Dec. 26. The entire mill will now be able to operate to full capacity for about 60 days.

Florence Goldfield—In a drift driven from the main company workings to connect with the Engineers Lease shaft on the 500-ft. level an entirely new body of bonanza ore has been found. The extent of this orebody has not been determined.

Keweenaw—Two new leases have been let on this claim about 400 ft. from the main workings where the company is doing considerable development work. Block 6 was leased to Elliott & Company, of Chicago, who agree to sink a two-compartment shaft to a depth of at least 500

ft. The lease runs eight months. Block No. 5 was leased to Charles Harrison, of Omaha. No stipulations were made as to depth required; this lease runs 18 months.

Old Kaintuck—The Iconoclast shaft has been retimbered to a depth of 180 ft. When these repairs reach the 200-ft. level, Hardy Brothers, who have leased the property, will start active development work.

C. O. D. Consolidated—The Gold Bar shaft, now 300 ft. deep, shows a wide body of gold-copper ore too low in grade to work at the present price of copper, but sufficiently mineralized to encourage further development.

Smith Florence Mining Company—This company has taken over the old sub-lease let to Mitchell & Fairfield on the Hall-Florence ground. The sub-lease contract called for the sinking of the Hall-Florence shaft from the 300-ft. to the 500-ft. level; this work is now in progress. The Smith block of ground will be entered by a drift only 10 ft. long from the shaft. Both the Smith and the Hall leases will be worked from this shaft.

Booth—The Murphy-Sweeney lease on the Booth has found ore of good shipping grade in a winze sunk from the north drift on the 400-ft. level.

Hazel Goldfield—At this lease on the Last Chance claim of the Laguna, the broken-up orebody, which was found some weeks ago on the 720-ft. level, has been found in place in the southwest drift about 30 ft. from the shaft. A 4-ft. body of ore in the breast of this drift averages \$42.50 per ton.

ESMERALDA COUNTY—LODI

Illinois Mine—A 100-ton smelter is being installed. All the machinery equipment for the smelter and shops has arrived at Luning on the Southern Pacific and is being hauled 50 miles to Lodi by the company's traction engine.

ESMERALDA COUNTY—SILVER PEAK

Silver Peak Valcald—The 10-stamp mill, now running to full capacity is to be increased to 40 stamps so as to have a capacity of 200 tons per day. M. J. O'Meara is president of the company.

Bay State & Nevada Oil Company—This company, which is drilling for oil near Blair has lost its string of tools at a depth of 517 ft. just subsequent to the securing of the first sample of oil from the hole. Fishing tools have been ordered from Los Angeles.

Goldfield Silver Peak Mining Company—At this property about 25 miles northwest of Goldfield at Coyote Springs in the Silver Peak quadrangle a ten-stamp mill and cyanide equipment is to be built. The property is controlled by the officials of the Clark railroad.

ESMERALDA COUNTY—HORNSILVER

Great Western—At this mine, which has been developing very well as a silver property, a vein of gold ore has opened up on the 300-ft. level. This gold discovery appears to be more important than the silver orebodies discovered in the past. The gasoline traction engine for hauling the ore to Cuprite has arrived.

HUMBOLDT COUNTY—CHAFEY

Black Hole Mine—The new shaft is down to the 105 ft. level where a station will be cut and drifts started on the ore. Sinking will be resumed as soon as possible. The main drift in the upper tunnel after passing through a pinch for 20 ft. has again come into a solid breast of ore. Another Huntington mill is being installed; this will increase the capacity of the mill to 50 tons.

ESMERALDA COUNTY—RAWHIDE

Victor—The Victor shaft is 300 ft. deep and is still in good ore. Ten feet of the ore averages \$34 per ton.

Rawhide Rector—In the Cooks and Waiters lease a crosscut is being driven to the vein.

Kerns No. 2 Lease—Recently ore has been found on the 200-ft. and 400-ft. levels so that now ore is developed on all the levels of the lease. In the nearby St. Ives lease milling ore has been found.

Hooligan Hill Leases—The Truett and the Miller leases are sacking ore for shipment.

HUMBOLDT COUNTY—SEVEN TROUGHS

Seven Troughs Mining Company—A test run on ore from this company's mine is being made at the Kindergarten mill to determine the best method for treating the ore. The company plans to build a ten-stamp mill.

Vernon Gold Prize Mining Company—A tunnel has been started on the west side of Gold Prize hill which will be run 250 ft. to prospect the hill.

Wihija Gold Mines Company—The Wihija lease on the Therein ground of the Seven Troughs Coalition Company has cut the rich Kindergarten shoot at a depth of 320 ft. in the incline shaft, or at a vertical depth of about 200 ft. This corresponds to the depth in the Kindergarten mine at which this vein has proved rich.

NYE COUNTY—TONOPAH

Production for the week ending Dec. 12 amounted to 5268 tons, having an estimated value (shipping ore valued at \$60 per ton and milling ore at \$25 per ton) of \$317,700. The Tonopah Mining Company sent to the mill 3000 tons; Belmont, 700; Montana-Tonopah, 593; Midway, 100; MacNamara, 375; West End, 150; Jim Butler, 350 tons.

Tonopah Mining Company—An advance of 10 ft. was made during the week in the Mizpah shaft, the total depth now being 1274 ft. The flow of water recently struck, and which was the first water found in the Tonopah mines, has impeded work. The flow has increased now to such volume that all sinking has stopped until pumps can be installed. The drill hole from the 740-ft. level is down 217 ft.; there is a slight change in the rock that the drill is passing through. At the mill at Millers 99 out of the 100 stamps during the week ending Dec. 12 treated 3210 tons of ore having an average value of \$23.50 per ton. Shipments consisted of 72 bars of bullion, weighing 77 lb. each, and worth \$815 per bar, and 50,000 lb. of concentrates valued at \$11,500. The extraction was 88 per cent.

German-American Mining Company—Arrangements are being completed to resume work on this property about a mile northwest of town. A contract has been let for sinking a new shaft at a point where surface indications are most favorable. The old shaft is 680 ft. deep.

Montana-Tonopah—The tonnage produced and milled this week was smaller than usual, due to necessary repairs in the mill. The tonnage treated was 970 tons, 593 tons coming from the company's mine and the rest from the MacNamara.

West End—Much development work is being done on the 200-ft. and 400-ft. levels. Quartz is being found in many different places; not all of this is rich enough to mine, but streaks of pay ore and large bunches of milling ore are being found.

NYE COUNTY—HELENA

Broken Hills—Tests are now being made in Denver on the ore so as to determine the process to be used in the 50-ton mill which the company intends to erect. J. C. McCormack, of Goldfield, is president and general manager.

NYE COUNTY—BULLFROG

Mayflower—Grab samples of the ore in the cars coming from the two raises on the 300-ft. level assay \$52.60 per ton. Similar samples of the ore coming from a length of 150 ft. along the main drift on the 300-ft. level average \$15.25 per ton.

CHURCHILL COUNTY—WONDER

Jack Pot Consolidated—The Jack Pot management assures the mine owners of the camp that they will put up a custom mill, and have asked for data that will enable them to decide the question of capacity.

WHITE PINE COUNTY

Grouse—The smelter burned Dec. 18. It had never been in operation.

New Mexico

GRANT COUNTY—SYLVANITE

Americus-Sylvanite Mines Company—This company has been organized to work three claims adjoining the Nederland property. The officers of the company are F. R. Berbower, of Cripple Creek, president; A. F. Hartman, of Sylvanite, vice-president and manager; M. E. O'Brien, of Cripple Creek, secretary and treasurer, and James F. Gray and E. J. Carlin, of Denver, are on the board of directors.

Sylvanite Consolidated Mining Company—This company has been organized to operate the eight claims known as the Holcomb property, southeast of Sylvanite. E. A. Wheeler and Milton Ish, of Goldfield, Nev., control the company. The stock of the new company will be placed on the market at once. It has four open cuts on its Clemmie claim from which rich ore is being sacked, and on which a two-compartment shaft was started this week. This property has the most extensive showing of any in the district. The vein from 10 to 30 ft. wide extends the full length of the property and can be traced to the Broken Jug and the Big John claims. The latter claim is being developed by the King Solomon Mining Company, which is sinking a shaft and driving two tunnels on its two claims. The work is in direct charge of Leonard Loehr, of Bisbee, manager of the company.

Wood Mine—The Pierson brothers, of Ouray, Colo., and W. E. Irwin, of Bisbee, Ariz., the new owners of the Wood mine, have closed a contract for hauling the ore from the mine to Hachita. From there the ore will be shipped to the smelters at Douglas. The whole breast of the tunnel, now 300 ft. long, is in ore.

Pennsylvania

ANTHRACITE COAL

Hillside Coal and Iron Company—The fire which destroyed the carpenter, blacksmith and machine shops at the Butler colliery Dec. 24 is a severe blow to the company, although the loss is partly covered by insurance. The building was a large wooden structure, complete in every detail and equipped with the latest machines and tools, the company having recently installed a large lathe and several other small machines in the machine shop in order to do the machine work at the colliery instead of sending it to local shops. The carpenter shop was connected with the blacksmith shop, and in it was done the work of repairing and rebuilding mine cars. All the tools belonging to the workmen were destroyed or ruined by the fire, besides many tools belonging to the company.

BITUMINOUS COAL

John W. Boileau, representing a Pittsburgh syndicate, has bought a tract of 6000 acres of coal land in Greene county, at a

price said to be \$250 per acre. The tract included in this purchase is in what is known as the North Waynesburg field, in Morris, Washington and Franklin townships, to the northeast of Waynesburg and along the Waynesburg & Washington railroad, the center of the tract being in the vicinity of Sycamore station. Geologically, the tract lies in what is known as the Waynesburg syncline, similarly located to that of the Pittsburg & Westmoreland Coal Company to the north, and adjoining the holdings of Frank M. Osborne & Co., and on the west of the tract lately purchased by the Emerald Coal Company. It is the last large tract available in this field.

South Dakota

CUSTER COUNTY

Ruberta—Superintendent W. W. Olds, of Custer, is employing a good force of men in sinking the two shafts west of Custer. One is down 180 ft. and the other 100 ft. and some ore showing has been made. The stamp mill is to have an addition of five stamps before spring.

LAWRENCE COUNTY

Branch Mint Operating Company—The 800-ton mill is making test runs of mine and dump ores, and if results are satisfactory, will be run steadily. President John Ohmeis, of New York City, is expected here shortly.

Homestake—The Pochontas mill has just changed its equipment and is now operated with electricity instead of steam. The other mills will soon be under the same motive power. Sinking in the Ellison shaft, the deepest in the Black hills, will probably soon be commenced again. It is now down 1750 and is to be deepened 150 ft. more.

Queen Esther—The shaft is now down 60 ft. and will be sunk to quartzite by Stewart Connors and associates of Deadwood. A good mineralization is showing in the present formations.

Tinton—The mill has closed for the winter, after a successful run. Superintendent E. W. Noakes, of Chicago, announces that a plant will be built in the spring.

Victoria Extension—New officers were elected at the annual meeting as follows: President, J. C. Carson, Deadwood; vice-president, W. M. Glass, Omaha; secretary and treasurer, A. J. Maltener, Deadwood; directors, A. B. Smith and T. L. Kounts, Omaha.

Victoria—It was decided at the annual meeting held here recently to start up the 200-ton cyanide mill again on a test run under the management of O. N. Brown. The ore reserves that show plenty of good-grade cyaniding ore will be sampled thoroughly and if practical, the mill will be kept in steady operation. The new officers elected are: President, A. B. Smith; vice-president, Arthur C. Smith,

Omaha; managing director, W. M. Glass, Omaha; secretary, treasurer and general manager, A. J. Maltener, Deadwood.

PENNINGTON COUNTY

Pilcher—Charles and Joseph Pilcher have discovered a ledge of free-milling gold ore near Rochford, and are preparing to develop it.

Utah

BEAVER COUNTY

Cedar Consolidated Mines Company—This company has been formed by the consolidation of the Cedar and the Talisman companies.

North American—The new shaft being sunk by contractors is now 100 ft. deep.

SALT LAKE COUNTY—ALTA

South Columbus Consolidated—Some time ago No. 1 drift east from the adit struck a broken-up body of copper ore. A raise driven from the adit has found this orebody in place. The vein is from 2½ to 3½ ft. wide and rich in copper. A winze has been started from the adit to catch this vein.

Columbus Consolidated—A body of good ore 4 to 10 ft. wide has been developed on the 400-ft. level for a distance of 80 ft. A raise has been started from that level to develop this orebody.

SUMMIT COUNTY

Shipments—Shipments from the Park City mines during the week ending Dec. 19 amounted to 1812 tons. The Silver King shipped 825 tons; Daly-West, 575; Daly-Judge, 304; American Flag, 109 tons.

Ontario Tunnel—There has been an increased flow of water coming through this tunnel the last few weeks. Evidently this is coming from the Daly-West mine, for the water in the Daly-West shaft is being lowered. The water course was struck in Ontario ground. The tunnel has been turned so as to follow this fracture which leads toward the Daly-West shaft.

TOOELE COUNTY—TINTIC

Shipments—The Tintic mines shipped 131 cars of ore during the week ending Dec. 18. The Sioux Consolidated shipped 14 cars; Iron Blossom, 4; Colorado, 16; Dragon Iron, 19; Black Jack, 1; Brooklyn, 3; Lower Mammoth, 3; Ajax, 3; Swansea, 2; Eureka Hill, 1; May Day, 1; Centennial Eureka, 44; Bullion Beck, 1; Yankee, 2; Uncle Sam, 6; East Tintic Development Company, 1; Utah Consolidated (leasers), 1; Grand Central, 9 cars. The cars from the Colorado, Dragon Iron, Brooklyn and Swansea mines were 20-ton cars, the rest 30-ton cars.

West Tintic—This mine belonging to the Nevada-Utah Development Company and in the West Tintic district made its first shipment last week. About 25 men are working at the mine.

Centennial Eureka—A sinking pump has been ordered to handle the water cut in the main shaft at a depth of 2100 ft. The shaft is making about 60 gal. of water an hour. Apparently this is a surface flow of water.

Ophongha Mining Company—This company has arranged to develop its property through the shaft workings of the Black Jack company. The 300-ft. and 1000-ft. levels of the Black Jack will be extended into Ophongha ground.

Iron Blossom—Copper ore has been found on the 800-ft. level.

TOOELE COUNTY—OPHIR

Lyon Hill Consolidated Mining Company—The first shipment from the orebody recently found in the adit assayed 255 oz. silver, 0.06 oz. gold and 7 per cent. lead per ton. In the winze below the adit the orebody is 14 ft. wide. The high-grade streak is in the center of the vein.

Ophir Hill and Cliff Mines—Twenty-five teams are hauling ore from the Ophir Hill mine, belonging to W. A. Clark, of Montana, and 20 teams from the Cliff property.

Canada

Arrangements have been entered into between the Ontario government, the town of Sudbury, and Mackenzie & Mann, of the Canadian Northern Railway, by which Mackenzie & Mann undertake the construction of a wagon road between Sudbury and Gowganda, a distance of 80 miles. A gang of men has been started on the work. Mackenzie & Mann are also surveying the country with a view to extending the Canadian Northern Ontario Railway into the Gowganda district.

Alfred von Hammerstein, who has been carrying on extensive petroleum development in northern Alberta, calls attention to the enormous waste of natural gas which has been going on for many years in that region. Fifteen years ago when drilling for oil was undertaken by the Canadian government at Pelican Portage on the Athabasca river, a tremendous flow of gas was struck at a depth of 800 ft., which made it impossible to proceed with operations; the flow has continued ever since, the government, in spite of the representations of those interested in the development of the district, having done nothing to stop it. An extended area is being drained.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore for the week ending Dec. 19 were as follows: Buffalo, 54,980 lb.; Crown Reserve, 120,000; City of Cobalt, 60,000; La Rose, 195,000; McKinley-Darragh, 115,800; Nipissing, 130,760; Right of Way, 62,100; Silver Queen, 67,000; Silver Cliff, 44,000; Temiskaming, 60,000; Trethewey, 131,000; total, 1,040,640 pounds.

Cobalt Central—The company is enlarging the capacity of its concentrating mill, and will soon begin the treatment of custom ores, having already made some contracts with neighboring mines.

La Rose—A rich vein recently struck on the O'Brien property runs into La Rose ground parallel to No. 3 vein; it will be worked from No. 3 shaft. No. 3 vein has widened at the bottom of the shaft to 4 in., and is yielding 5000 oz. of silver to the ton. At the University mine the shaft on No. 4 vein is down 50 ft. with ore showing all the way averaging 3000 oz. to the ton.

Nipissing—A new vein has been encountered in crosscutting at the 75-ft. level from the Fourth of July shaft; it is thought to be vein No. 100; it is 3 in. wide and carries high-grade ore. The shaft is being sunk to the 150-ft. level. The new ore house at this shaft is completed. At the 75-ft. level of the Meyer shaft the vein, averaging 5 in. wide, has been drifted on for 150 ft., and is yielding well. No. 6 shaft, near the Temiskaming & Hudson Bay boundary, is down 75 on a wide calcite vein. In drifting 300 ft. east of the Kendall shaft at the 145-ft. level a new cross-vein, carrying between 3 and 8 in. of good ore was struck. A quarterly dividend of 3 per cent. with a bonus of 2 per cent. has been declared, payable Jan. 20, 1909.

ONTARIO—LARDER LAKE DISTRICT

Dr Reddick—The closing down of the stamp mill was caused by a bad break in the Gates ore crusher, weighing between three and four tons. Owing to transportation difficulties, some time will elapse before the crusher can be put in working order.

ONTARIO—WELLAND COUNTY

Coniagas Smelter—About two tons of silver, the output of this smelter at Thorold, were shipped to New York this week.

Big Six—Six veins have been found, two of which look promising. The main shaft is down 50 ft. on an 8-in. calcite vein, assaying 700 to 800 oz. silver to the ton. A 6-in. cobalt vein carries argentite and native silver.

ONTARIO—SOUTH LORRAINE DISTRICT

Jacobs Exploration Company—On the Wiltsey property, owned by this company, a 3-in. smallite vein carrying native silver has been found, and ore is being taken from a test pit.

ONTARIO—GOWGANDA LAKE DISTRICT

McIntosh and McLaughlin Location—F. A. McIntosh and Samuel C. McLaughlin have disposed of their claim, said to be a rich one, to a syndicate of British and American capitalists; the price is reported to be about \$500,000. The property will be known as the Bartlett mine.

NOVA SCOTIA

Nova Scotia Steel and Coal Company—The output of coal for the 10 months ending November was 601,294 tons, as compared with 575,693 tons for the corresponding 10 months of 1907.

Mexico

GUANAJUATO

Shipments—The value of the shipments for the week ending Dec. 17 amounted to \$290,000 including concentrates, bullion and high-grade ore. Bullion shipments amounted to \$180,000. The closing of the mill announced last week will make little difference in the total production; the loss will be made up by the increased output of the Perigrina mine.

El Cubo—The tunnel driven to tap the Villalpando shaft has been completed. The tunnel which is 7000 ft. long was started from both ends; it will be used to facilitate handling the ore and the water from the lower levels.

Tepeyac Incline—The double-track surface incline from the patio of this mine of the Guanajuato Reduction and Mines Company has been completed. It will carry the ore from the San Antonio dump to the head of the aerial tramway which will deliver it to the Bustos mill.

Providencia—The foundations for the mill are nearly completed and plans for the equipment are practically finished. The plans call for stamps weighing 1350 lb. There will be 40 stamps, three tube mills, concentrating tables and a cyanide department. Work will be started shortly after the first of the year and rushed to an early completion, in order to handle the ore that is being taken out.

TEPIC

Guanajuatillo—A hydroelectric power plant will be installed to unwater this old mine of the Castellana group which has been abandoned for 100 years.

SONORA

Greene-Cananea—The fifth and sixth furnaces were blown in last week. Not an extra man was required in the operating of the ore-handling machinery. The only increase was a few men to attend each furnace. The contributing factors to the increased output following the blowing in of the two stacks are the Capote, Oversight, Cananea-Duluth and Cananea Central. The Capote output is a sulphide ore, while in the upper levels of the Oversight there have recently been made available large orebodies of higher than average grade. The Cananea-Duluth is now opened for supplying 500 tons daily for a period of five years. The company is treating 3000 tons of ore daily, from which the gold and silver recovery are equal to 1½¢. per lb. of copper produced.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, Dec. 30—The coal trade in the West improves slowly, if at all, and the closing week of the year brings reports of only moderate activity. Continued mild weather keeps down domestic demand, and the call for steam coal is not large. Operators hope that cold weather and the opening of the new year will bring more orders.

The Seaboard bituminous trade is also quiet, and business is only of a moderate character. The steam-coal demand is not improving, but some of the dullness reported is due to the holidays.

Anthracite continues to be a weaker market mainly, and not much improvement can be expected until colder weather sets in throughout the East.

Discrimination in Anthracite Rates—M. J. Healey, of Wilkes-Barre, Penn., this week was successful in his contention before the Interstate Commerce Commission that the Lehigh Valley Railroad Company had discriminated against him in rates in the haulage of coal from the Miner's Mills colliery, of which he has the management. Healey had two complaints against this corporation, one as the result of the business done at Miner's Mills and the other in the alleged unfair treatment of the Reliance Coal Company at Pittston, a concern of which he has control. It was on the first grievance the commission heard testimony. The latter one will be gone into later. The argument of the Plains operator was so well substantiated that the attorneys representing the company decided to settle and thus save themselves from the punishment provided for rate discrimination. As a result the Miner's Mills Coal Company will be reimbursed for the excess in rates which has been paid during the entire time in which it shipped coal, a period of four years. The outcome of the protest of Healey is the first instance in which an individual anthracite-coal operator has carried his objections to a successful issue.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania lines east of Pittsburg and Erie, call for Dec. 10, in short tons.

	1907.	1908.	Changes.
Anthracite.....	5,643,927	5,047,146	D. 496,781
Bituminous.....	38,907,479	33,153,039	D. 5,754,439
Coke.....	12,932,012	7,006,528	D. 5,925,484
Total.....	57,392,812	45,206,713	D. 12,176,099

The total decrease this year to date was 21.2 per cent.

The total coal passing through the Sault canals up to the final close of the season was, in short tons:

	1907.	1908.	Changes.
Anthracite.....	1,506,668	1,384,743	D. 121,925
Bituminous....	9,493,427	8,517,717	D. 1,375,710
Total.....	11,400,095	9,902,460	D. 1,497,635

Coal receipts at Milwaukee by Lake for the season were: Anthracite, 1,076,812 tons, an increase of 194,943 tons; bituminous, 2,584,355 tons, a decrease of 642,666 tons; total, 3,661,167 tons, a decrease of 447,753 tons.

Coal receipts at St. Louis, 10 months ended Oct. 31 were 6,597,393 tons in 1907, and 5,618,083 in 1908; a decrease of 979,310 tons.

Coal shipments by water from Seattle and Tacoma, Wash., 10 months ended Oct. 31, were 502,907 short tons in 1907, and 359,945 in 1908; a decrease of 151,962 tons. Nearly all these shipments are coastwise, to California and Alaska ports.

Coastwise coal shipments from Atlantic ports, 10 months ended Oct. 31, long tons:

	Anthracite.	Bitum.	Total.	Perc't.
New York.....	12,368,886	8,361,263	20,730,149	62.4
Philadelphia	1,756,989	3,886,655	5,643,644	17.0
Baltimore.....	203,046	3,032,342	3,235,388	9.7
New York News		2,259,934	2,259,934	6.8
Norfolk.....		1,374,701	1,374,701	4.1
Total.....	14,328,921	18,915,495	33,244,416	100.0
Total, 1907, 16,031,621	20,419,383	36,451,004		

Total decrease this year was 3,206,588 tons, or 8.8 per cent. New York includes all the New York harbor shipping ports.

New York

ANTHRACITE

Dec. 30—The hard-coal market is lifeless, and little business is being done either in prepared or small steam sizes. Schedule prices are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam prices are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50. All prices are f.o.b. New York harbor points.

BITUMINOUS

The soft-coal trade, as a whole, continues dull. The all-rail trade is a little more active than tidewater, and along the Sound more coal is being taken than in the far East. New York harbor is at a standstill.

Consumers are holding off until after Jan. 1, or, if they agree to take coal, they ask that part of the consignment be billed against the new year. Transportation is good and cars are plentiful. Prices in

New York harbor remain at \$2.45@2.65 per ton.

In the Coastwise vessel trade vessels are scarce, but the demand is light. Freight rates are slightly firmer as follows, from Philadelphia: To Boston and Portland, 75c.; Salem, Lynn and Bath, 85c.; Newburyport, 95c.; Portsmouth, 80c.; Providence, New Bedford and the Sound, 65@70c. per ton.

Birmingham

Dec. 28—The coal operations throughout Alabama will resume on a firm basis next week. It is understood that there will be a resumption at several of the mines which have been idle for some time, while mines which have been in operation will add to their force of employees. Miners are looking forward to the coming month for steady work. Sales agents report that there has been a good inquiry for coal and that orders are in hand or promised that will keep the mines going through the better part of the coming year.

Coke is still in strong demand and the production is being kept at a high mark.

Chicago

Dec. 28—Mild weather and partial suspension of steam needs because of the holidays have made demand for steam coals light in the last week, but shipments to this market have also been light on account of closing of the mines for Christmas and there is little trouble about oversupply. Domestic coals are in general lagging because of the weather. Steam coals show increased demand from week to week and Illinois coals are stronger than for several weeks.

Lump and egg from Illinois and Indiana mines sell for \$1.80@2.60; run-of-mine brings \$1.05@1.75 and screenings are in good demand at \$1.20@1.50. Fine coals are exceptionally strong.

Of coals from east of Indiana, smokeless is weakest, receipts being large and sales lagging. Pocahontas and New River smokeless bring \$3.80@4.05 for lump, and \$3.05@3.15 for run-of-mine. Lower-grade smokeless is abundant at as low as \$3.15 for lump and \$2.75 for run-of-mine. Hoeking has been overabundant, but is firm in tone with the surplus well disposed of, and holds well above the \$3 mark, though selling last week for 10 or 15c. less. Youghiogheny is quiet at \$3.15 for 4-in. gas.

Anthracite is in plentiful supply and light demand and all sizes are in good supply.

Cleveland

Dec. 29.—Business looks a little better, owing to some improvement in purchases of steam coal. The demand for slack just now is better than that for lump and screened coal. Prices for slack are, therefore, relatively higher. Pittsburg No. 8 and Middle District slack bring 70¢@75¢ at mine; Massillon slack, 60¢@65¢ at mine. Domestic coals are quiet, with light demand. Massillon lump is \$3.10@3.15, Cleveland.

Pittsburg

Dec. 29.—Holiday stops and other conditions have combined to make a very dull market for the close of the year. It is difficult to make an estimate of the conditions at the mines, owing to the cutting out of several working days. Prices are nominally maintained at \$1.15 for run-of-mine coal at mine; but sales have been small. The best demand has been for slack.

Connellsville Coke.—No change in coke conditions can be reported, as consumers still hesitate about placing contracts for 1909. Present indications, however, are that they will not gain anything by holding back, as prices likely will not decline. Furnace coke for first-half delivery is quoted at \$2; foundry at \$2.25@2.40, f.o.b. ovens. For spot shipment these prices may be shaded a little, though the disposition to shade is gradually disappearing. Production is increasing; the *Courier* reports this week 251,093 tons, the highest weekly report for the year. The total, by these reports, for the year to Dec. 19, was 9,117,838 tons. To the corresponding date in 1907 the total was 10,155,971 tons, the decrease this year being 10,038,073 tons, or 52.4 per cent. Production is better now than last December, however, this week showing an increase of 113,651 tons over the corresponding week in 1907. Shipments for the week were 9,305 cars, divided as follows: To Pittsburg district, 3310; to points west of Pittsburg, 5248; to points east of Connellsville, 747 cars.

Foreign Coal Trade

Belgian Coal Trade.—Imports and exports of fuel in Belgium, 11 months ended Nov. 30, metric tons:

	Imports.	Exports.	Excess.
Coal.....	4,884,110	4,356,990	Imp. 527,111
Coke.....	267,335	835,713	Exp. 568,378
Briquets.....	167,010	448,486	Exp. 281,476
Total.....	5,318,455	5,641,198	Exp. 322,743
Total, 1907.....	5,296,712	5,542,721	Exp. 246,009

Imports are chiefly from Germany and Great Britain; exports principally to France and Luxemburg.

French Coal Trade.—Imports and ex-

ports of fuel in France, 10 months ended Oct. 31, metric tons:

	Imports.	Exports.	Excess.
Coal.....	12,242,100	894,210	Imp. 11,347,890
Coke.....	1,520,180	114,020	Imp. 1,406,160
Briquets.....	875,660	108,210	Imp. 767,450
Total.....	14,637,940	1,116,440	Imp. 13,521,500
Total, 1907.....	14,518,570	1,191,100	Imp. 13,327,470

Included in the exports this year are 134,260 tons of coal and briquets furnished to steamships in foreign trade.

Nova Scotia Coal.—Shipments of Nova Scotia coal for the 11 months ended Nov. 30 are reported as follows, in long tons:

Company:	1907.	1908.	Changes.
Dominion.....	3,018,155	3,049,104	I. 30,949
Nova Scotia Steel.....	575,693	601,214	I. 25,521
Cumberland.....	242,150	322,225	I. 80,075
Acadia.....	294,557	294,403	D. 154
Inverness.....	221,104	240,871	I. 19,767
Intercolonial.....	251,823	226,067	D. 25,756
Total.....	4,603,482	4,743,964	I. 140,482

One company showed a decrease and one was about stationary. The total increase was 3.1 per cent.

German Coal Trade.—Imports and exports of fuel in Germany, 10 months ended Oct. 30, metric tons:

Imports:	1907.	1908.	Changes.
Coal.....	11,358,689	9,765,314	D. 1,593,375
Brown coal.....	7,422,418	7,157,580	D. 264,838
Total coal.....	18,781,107	16,922,894	D. 1,858,213
Coke.....	346,946	360,756	I. 13,810
Briquets.....	154,992	155,981	I. 989

Exports:				
Coal.....	16,457,105	17,442,980	I.	985,875
Brown coal.....	17,334	22,600	I.	5,266
Total coal.....	16,474,439	17,465,580	I.	991,141
Coke.....	3,197,723	3,011,127	D.	126,596
Briquets.....	1,006,932	1,268,570	I.	261,638

Exports this year include 2,3775 tons coke to the United States.

Welsh Coal Prices.—Messrs. Hull, Blyth & Co., London and Cardiff, report prices as follows on Dec. 19: Best Welsh steam, \$3.48; seconds, \$3.36; thirds, \$3.24; dry coals, \$3.00; best Monmouthshire, \$3.18; seconds, \$3.06; best small steam, \$2.04; thirds, \$1.74. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, Dec. 30.—The volume of business transacted has continued light, even less than last week. This is due in large part to the holiday season, when there is always a lull in trade. It is to be observed, however, that specifications on contracts are coming in slowly, which is not a good sign. Business also has been affected by the tariff discussion, and the general belief that the iron and steel schedules will be revised, if there is any change at all. The impression is that Congress will feel compelled to do something to satisfy popular demand for revision. The discussions before the Ways and Means Committee have undoubtedly given an impetus to this feeling. Pig iron orders have been few this week and generally small. Foundries have been buying only for immediate needs, and seem to be in no hurry to provide for the future. There is a little

more call for basic iron, but it is hardly to be called active. Southern furnaces seem to be better provided with orders than Northern; at any rate they are not hunting for business.

In finished material orders and specifications are both slow. There is talk of contracts, but actual sales are put off to next month. This is the result of the holiday season, probably, and so only a passing condition. There is reason to believe that structural material will soon make a better showing, especially if there is no attempt made to advance prices, or to enforce nominal quotations. Contrary to general belief, it is probable that the amount of structural business in 1908 will make a good showing, compared with the previous year. This cannot be said of any other branch of the iron and steel trade.

Other railroads are slow in following the example of the Pennsylvania, and no considerable orders for rails have been placed. Several roads are said to be figuring on large orders, but they are not yet ready. In view of the comparatively light repairs and renewals made in 1908, it is evident that a large tonnage for 1909 will be needed.

Lake Superior Iron Ore.—The *Marine Review*, of Cleveland, reports that the final shipment of ore for the season of 1908 was taken by the steamer "W. D. Rees" from Escanaba to Milwaukee, consisting of 5349 tons. December shipments were therefore 78,924 tons. Shipments for the past three years by ports have been as follows:

Port.	1906.	1907.	1908.
Escanaba.....	5,851,050	5,761,088	3,351,502
Marquette.....	2,791,033	3,013,826	1,457,487
Ashland.....	3,388,112	3,437,672	2,513,670
Superior.....	6,083,057	7,440,386	3,564,030
Duluth.....	11,220,218	13,415,377	8,808,168
Two Harbors.....	8,180,125	8,188,906	5,702,237

Total. 37,513,595 41,288,755 25,427,094
The season of 1908 shows a decrease of 15,801,661 tons, or 38.4 per cent., as compared with 1907; and a decrease of 12,080,501 tons, or 32.2 per cent., as compared with 1906.

Baltimore

Dec. 29.—Exports for the week included 2,747,500 lb. steel billets to Liverpool; 429,129 lb. structural steel and 2,888,165 lb. steel plates to Panama; 287,360 lb. spelter to Liverpool. Imports included 420 tons ferromanganese from Germany, and 4950 tons iron ore from Cuba.

Birmingham

Dec. 28.—Southern pig-iron manufacturers look for a decided change again in the general conditions, both as to buying and as to quotations before the middle of January. There is some inquiry for iron for future delivery, but the holiday quietness has been on for three or four days. However, there is a good feeling prevailing; the order books are supplied for the

coming three months and some sales have already been booked for the second quarter. A few lots of iron were sold before the quietness set in at prices above \$13 per ton, No. 2 foundry. The make during the holiday season in the Birmingham district was not disturbed. The furnace records were maintained, and only for a day or two did the common labor appear to be restless. Pay days were arranged with the labor at the ore mines, coke ovens, limestone quarters and at the furnaces so that there would be no trouble in providing for the usual festivities of this season. The Tennessee Coal, Iron and Railroad Company has arranged to blow in its No. 6 furnace at Ensley this week while preparations are being made to start other furnaces in this territory.

Chicago

Dec. 28—Buying of pig iron is very light, the holiday effect being perceptible in every line of business. Inquiries are very few and the small amount of buying being done is on early deliveries. There is said to be no weakening of prices, for the reason that furnace agents as well as users of pig iron are contented to await the developments of the new year. With both sides waiting, the general iron market shows no other signs of weakness, the outlook in finished products being good, though business is dull generally.

Southern No. 2 holds at \$13 Birmingham (\$17.35 Chicago) as a minimum, and Northern No. 2 to \$17, with Lake Superior charcoal selling at \$19.50@20, for delivery within the next three months. For the second quarter 25@50c. more is asked, though the lack of any good-sized transactions makes it difficult to say what a good contract could be placed for.

Coke remains weak, being in large supply and poor demand at \$4.90 for the best Connellsville.

Philadelphia

Dec. 30—Basic pig iron is in active demand, the largest transaction of the past week being for the delivery of 20,000 tons as called for monthly, the entire delivery to be completed by June 30, if desired. Business into which basic pig enters is improving steadily, and negotiations are pending for additional sales. Forge demand is increasing at central and eastern Pennsylvania mills, but these requirements are filled only as new orders for material come in. Foundrymen have been poor buyers for several weeks, and as furnacemen are not driving after business, sales are moderate and mostly on furnace terms. Southern furnaces are not a threatening factor at present, but when they get hungry for business along in February or March there may be some developments unfavorable to Pennsylvania furnace interests. The volume of business since Oct. 1, when averaged up, shows a

steady increase under the policy of buying only what was needed.

Pipes and Tubes—A sharp improvement has taken place in tubes. Boiler-repair work and new boiler work is coming along nicely.

Plates—The favorable conditions in Western mills are reflected in Eastern. The past week has been quiet, but there is a large amount of work in sight.

Structural Material—No large orders have been placed. Several are pending, mostly for bridge and general construction work.

Old Material—In a general way scrap is held too high to induce consumers to buy more than they are obliged to. Dealers are slow to sell, except at their own terms, and they are urgently gathering in all the good qualities they can get, particularly heavy steel scrap. No. 1 yard scrap is held high. There is no railroad scrap offered, and the companies are refusing to sell at present.

Pittsburg

Dec. 29—The iron and steel markets this week have shown little or no change from the previous week. Sales have been light, as might be expected in a holiday week. No estimate can be made of mill operation, as most of the active works were closed down over the Christmas holiday. Some plants closed for the week, but quite a number have stopped until after New Year's, to give them a chance to make necessary repairs. Orders in most of them are not urgent enough to compel an early resumption.

Little news has developed on the rail question. It is understood that several companies are preparing to place rail orders, but none has yet followed the Pennsylvania example, and most of them are still waiting. Several railroad orders for equipment are pending, however, which will require large quantities of material.

Structural business shows no new developments, none of the large contracts pending having been closed this week. New trade continues good, and much activity is expected in January. Tinplate also shows a continuation of the good run of trade recently reported.

Pig Iron—Transactions have been very light, but inquiries are reported to be coming in, so that sellers are inclined to be firm in their views as to price. The starting up of some of the new furnaces at the big Gary plant of the Steel Corporation will not have any effect on the market, as the product will be used by the corporation. Prices show no material change. Quotations for first quarter are as follows: Standard bessemer, \$16.50@17; No. 2 foundry, \$16@16.25; malleable bessemer and basic, \$15.75@16; gray forge, \$14.50@15; all f.o.b. Valley furnaces.

Steel—There have been but few transactions in crude steel, and moderate deliveries made on contract. The price of both bessemer and open-hearth billets remains firm at \$25, Pittsburg. Tank plate is quoted at 1.60c. and merchant-steel bars at 1.40 cents.

Sheets—The sheet trade continues good for a dull period and prices are strong. Black sheets are quoted at 2.50c. and galvanized sheets at 3.55c. for No. 28 gauge.

Ferro-manganese—There is no change in the ferro market and quotations continue around \$47 per ton.

Foreign Iron Trade

Belgian Iron Production—Pig-iron production in Belgium in October was 105,000 metric tons; for the 10 months ended Oct. 31 it was 1,185,270 tons in 1907, and 987,570 in 1908; decrease, 197,700 tons.

German Iron Production—The German Iron and Steel Union reports pig-iron production in Germany in November at 930,738 metric tons, being 10,844 tons less than in October. For the 11 months ended Nov. 30 the production was, in metric tons:

	1907.	1908.	Changes.
Foundry iron	2,463,009	2,058,775	D. 4,294
Forge iron	717,949	585,537	D. 132,412
Steel pig	947,891	836,830	D. 111,061
Bessemer pig	432,617	339,295	D. 93,322
Thomas(basic)pig	7,777,959	6,976,348	D. 801,411
Total	11,899,385	10,796,985	D. 1,142,400

The total decrease was 9.6 per cent. Steel pig includes spiegeleisen, ferromanganese, ferrosilicon and all similar alloys.

Metal Markets

New York, Dec. 30—The metal markets are still rather quiet as the end of the year is reached. Some speculative activity is manifest, and sales to consumers have been fair.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Nov. 1908.	\$ 2,967,705	\$ 2,892,225	Exp. \$ 75,570
" 1907.	615,169	63,574,871	Imp. 62,959,702
Year 1908.	73,857,749	45,105,938	Exp. 28,750,846
" 1907.	54,211,240	38,949,557	Imp. 44,738,311
Silver:			
Nov. 1908.	3,951,987	3,275,600	Exp. 676,378
" 1907.	4,187,378	3,602,405	" 684,973
Year 1908.	47,111,382	37,814,676	" 9,296,706
" 1907.	67,212,168	41,690,324	" 15,621,844

Exports of specie from New York, week ended Dec. 26: Gold, \$801,010, to Paris and Panama; silver, \$484,007, chiefly to London. Imports: Gold, \$171,828; silver, \$64,009, from Australia, the West Indies and Mexico.

The Bank of France continues to take gold from this country and from the open market in London. Partly this is due to

the prospective placing of a new Russian loan shortly, a considerable part of which will be taken, in Paris. The Bank of France in its reserves this week reported \$697,678,100 gold and \$177,925,925 silver; a total of \$875,604,025 specie. The gold held is \$159,490,455 more than at the same time last year.

Gold—The open-market price reported for bar gold in London is 77s. 9½d. per oz.; for American eagles, 76s. 5d. per oz. Most of the gold offered went to France. No more gold is reported taken in New York for export abroad, and none, probably, will be taken until exchange hardens.

Platinum—This has been naturally a quiet week, but the market is strong, and an advance is expected. Dealers quote the same prices, however, as for some weeks past: \$24 per oz. for refined platinum, \$26.50 for hard, and \$20.21 for scrap; in some cases 25¢ more.

Our special correspondent reports that in Russia prices are firm, owing to increased demand, especially from abroad. At Ekaterinburg—center of the Ural platinum industry—crude platinum, called in Russia light platinum, and carrying 83 per cent. pure metal, is quoted at 5 rubles 10 kopeks per zolotnik, equivalent to \$19.16 per troy ounce. In St. Petersburg the principal dealers are offering considerable quantities of the same grade of metal at 5 rubles 20 kopeks per zolotnik, equivalent to \$19.57 per ounce.

Silver—Silver seems to have touched bottom for the present. A more cheerful feeling in India, with buying by the China banks and covering by speculators has taken the edge off the bearish tendency. Advices received here are that the outlook for 1909 is more hopeful than was recently believed.

SILVER AND STERLING EXCHANGE.

December.	24	25	26	28	29	30
New York....	49½		49½	49½	49½	50½
London.....	22½		22½	22½	22½	23½
Sterling Ex..	4.8700		4.8090	4.8700	4.8605	4.8700

New York quotations, cents per ounce troy, fine silver; London, pence per ounce sterling silver, 0.925 fine.

Shipments of silver from London to the East, year to Dec. 17; reported by Messrs. Pixley & Abell, London:

	1907.	1908.	Changes.
India.....	£10,531,354	£8,412,390	D. £2,118,964
China.....	417,350	641,400	I. 224,050
Straits.....	691,150	164,885	D. 526,265
Total.....	£11,639,854	£9,218,675	D. £2,421,179

Imports for the week £6000 from Mexico, £5000 from the West Indies, £18,400 from New York; total, £195,000. Exports £1500 to Egypt, £35,000 to India; £36,500 in all.

The United States Mint has resumed purchases of silver. On Dec. 23 the treasury Department bought 125,000 oz., 75,000 oz. for delivery at New Orleans and 50,000 oz. at Denver. The price paid was 49.118c. per oz., delivered.

Copper, Tin, Lead and Zinc

Dec.	Copper.			Tin.		Lead.		Spelter.	
	Lake, Cts. per lb.	Electrolytic, Cts. per lb.	London, 2 per lb.	Cts. per lb.	Cts. per lb.	Cts. per lb.	Cts. per lb.	New York, Cts. per lb.	St. Louis, Cts. per lb.
24	14½	14	63½	29½	4.12½	5.12½	4.97½	5.12½	4.97½
25	14½	14	63½	29½	4.15	5.15	5.00	5.15	5.00
26	14½	14		29	4.12½	5.12½	4.97½	5.12½	4.97½
27	14½	14		29	4.15	5.15	5.00	5.15	5.00
28	14½	14	63½	29	4.12½	5.12½	4.97½	5.12½	4.97½
29	14½	14	63½	29	4.15	5.15	5.00	5.15	5.00
30	14½	14	63½	29	4.12½	5.12½	4.97½	5.12½	4.97½
31	14½	14	63½	29	4.15	5.15	5.00	5.15	5.00

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—A persistent buying movement has developed in the market, resulting in a rather heavy business in electrolytic copper both for domestic and foreign account. As a result, prices have advanced and the close is firm at 14½@14½c. for Lake copper; 14½@14½c. for electrolytic copper in ingots, cakes and wirebars. The average for casting copper has been 13½@14½ cents.

Copper sheets, cold-rolled, 20c.; hot-rolled, 19c. per lb. Wire 15½c. base, car-load lots at mill.

The improvement in the London standard market has made further progress and the close is cabled firm at £63 16s. 3d. for spot, £64 12s. 6d. for three months.

Refined and manufactured sorts we quote: English tough, £67; best selected, £66@67; strong sheets, £78@79.

Copper exports from New York and Philadelphia for the week, 5102 long tons. Our special correspondent states exports from Baltimore for the week at 1288 long tons of copper.

Exports of copper in metallic form from the United States for the 10 months ended Oct. 31 were divided as follows, in pounds:

N. American countries.....	3,430,075
Germany and Holland.....	282,511,770
Great Britain.....	106,608,106
France.....	94,396,974
Other European countries.....	64,594,885
China.....	13,735,889
Other countries.....	2,437,553
Total.....	608,345,269

Exports of ores and matte were: Canada, 48,802; Mexico, 6209; other countries, 715; total, 55,726 long tons. The renewal of shipments to China is a feature of the present year of which little notice has been taken.

Tin—The market has been in a very unsatisfactory state, and London quotations

show rather a disposition to sag. This condition no doubt is brought about by apprehension of an unfavorable statistical position to be exposed at the end of this month. The market closes weak at £131 7s. 6d. for spot, £133 for three months.

Buyers in the domestic market continue to be very reluctant with regard to placing larger orders, and the little business that is being transacted is done at about 28½@29 cents.

Lead—Transactions in this metal have been a negligible quantity. Some inquiries are reported for distant delivery, which have not yet developed into actual business. It would, however, indicate that the impression is gaining ground that present prices cannot be far from bottom. The market closes unchanged at 4.12½@4.15c. New York, and 3.97½@4c., St. Louis.

The London market is somewhat lower, but steady at the decline, the close being cabled at £13 for Spanish lead, £13 2s. 6d. for English lead.

Spelter—Consumers have shown little interest in the market during the entire week. On the other hand, there is not much offered for sale on account of orders already booked by the smelters and the high prices for raw material. The market closes unchanged at 5.12½@5.15c., New York, 4.97½@5c., St. Louis.

The London market is firmer at £21 per ton for good ordinaries, £21 5s. for specials.

Base price of sheet zinc is 7c. f.o.b. La Salle-Peru, Ill., less 8 per cent.

Other Metals

Antimony—No sales were made during the week and prices remain unchanged. Quotations are 8.15@8.25c. for Cookson's; 8@8½c. for Hallett's and 7½@7¾c. for ordinary brands.

Aluminum—Prices continue unchanged. The Aluminum Company of America quotes 24c. per lb. base for No. 1 ingots, and 33@34c. base for sheets. Offers of foreign metal are still made at 22c. Actual sales are reported to be small. The foreign market is still demoralized, with prices low.

Nickel—Large lots, contract business, 40@45c. per lb. On retail business the price ranges from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. These quotations are for spot nickel. The price for electrolytic is 5c. higher.

Quicksilver—A slight degree of activity has developed during the week, but the market is only moderately active. New York prices are unchanged, at \$45@46 per flask of 75 lb. San Francisco quotations are \$45 per flask for domestic orders and \$43 for export. The London price is steady at £8 10s. per flask, with £8 8s. named by jobbers.

Cadmium—In 100-lb. lots, 75c. per lb., at Cleveland, Ohio.

Magnesium—This metal is offered in New York at \$1.25 per lb. in 100-lb. lots. The price is \$1.40 per lb. for 5-lb. lots.

Spanish Metal Exports

Exports of metals and ores from Spain, 10 months ended Oct. 31, metric tons, as reported by *Revista Minera*:

Metals:	1907.	1908.	Changes
Copper.....	7,085	11,744	I. 4,659
Copper precipitate.....	15,601	16,789	I. 1,288
Zinc.....	1,294	1,386	I. 92
Lead.....	158,479	158,000	D. 479
Quicksilver.....	1,197	1,504	I. 7
Minerals:			
Iron ore.....	7,444,274	6,329,310	D. 1,104,964
Copper ore.....	1,022,678	986,714	D. 35,964
Zinc ore.....	128,994	100,844	D. 28,150
Lead ore.....	4,742	2,003	D. 2,739
Manganese ore.....	17,217	18,443	D. 38,874
Pyrites.....	1,116,462	1,228,576	I. 112,114

Exports of salt, 423,262 tons in 1907, and 495,842 in 1908; increase, 72,580 tons.

Sault Ste. Marie Canal Traffic

The total traffic through the Sault Ste. Marie canals for the season was 58,217,214 short tons of freight in 1907, and 41,390,557 in 1908; a decrease of 16,826,657 tons, or 29 per cent. The number of vessel passages in 1908 was 15,181, showing an average cargo of 2726 tons. The mineral freights included in the totals were as follows, in net tons, excepting salt, which is in barrels:

	1907.	1908.	Changes.
Coal.....	11,400,095	9,902,460	D. 1,497,635
Iron ore.....	39,594,044	24,650,340	D. 14,943,704
Pig and manuf. iron.....	307,941	289,308	D. 18,633
Copper.....	89,959	101,735	I. 11,776
Building stone.....	898	1,019	I. 121
Salt, bbls.....	460,802	547,223	I. 86,421

The United States canal was open in 1908, April 27-Dec. 13, inclusive, or 231 days. The Canadian canal was open April 21-Dec. 15, or 239 days. There were no serious blocks or delays during the season.

Lake Freight Rates—The *Marine Review*, of Cleveland, reports the season average of freight rates on coal and iron ore as follows, in cents per ton:

	1906.	1907.	1908.
Anthracite.....			
Lake Erie ports to Chicago.....	46.20	40.78	40.00
Lake Erie ports to Duluth.....	35.19	31.26	30.00
Bituminous Coal:			
Lake Erie ports to Chicago.....	46.05	40.00	40.00
Lake Erie ports to Duluth.....	34.85	30.00	30.00
Iron ore:			
Escanaba to Lake Erie ports.....	60.00	60.00	60.00
Marquette.....	70.00	70.00	60.00
Duluth.....	75.00	75.00	60.00

This season there were practically no wild rates, all the business being done on contract.

Zinc and Lead Ore Markets

Platteville, Wis., Dec. 26—The highest price paid for zinc ore this week was \$44.50, on a basis of \$416.42 per ton of 60 per cent. zinc. For 80 per cent. lead ore \$50 per ton was paid.

SHIPMENTS, WEEK ENDED DEC. 26

In addition to the above there was shipped to the Joplin Separator Works, 350,000 lb.; to the Platteville Separating Company, 605,900 lb. zinc ore.

Joplin, Mo., Dec. 26—The highest price paid for zinc ore during 1908 was \$47 per ton, two weeks ago. The lowest price of high-grade ore was \$36.50 the second week of June, and the average price, all grades, for the year, was \$34.34. The highest price of zinc sulphide ore the past week was \$45 per ton, on an assay base price ranging from \$39 to \$42 per ton of 60 per cent. zinc. The highest price for zinc silicate was \$23, on an assay base price of \$17.18 per ton of 40 per cent. zinc. The average price for the week, all grades, was \$38.38 per ton. The highest price paid for lead ore was \$50, declining to \$38 at the

NOTE.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all grades. Lead ore prices are the average for all ores sold.

week-end, averaging for the week, all grades, \$48.82 per ton.

Christmas observation reduced the output about 30 per cent., and, with an average shipment, the reserve stock was reduced approximately 1300 tons, the first important decrease since the beginning of the heavy purchases. The decrease of the year is 29,417 tons of zinc, at a decrease in value of \$3,691,615 and 3701 tons of lead, at a decrease in value of \$791,906. The total decrease in value was \$4,483,521 for the year.

Chemicals

New York, Dec. 30—The market is steady and trading is quiet. The possible revisions of the tariff tend to restrict business for the time being. On the whole business is up to expectations.

Copper Sulphate—The market is firm and outside dealers are not shading standard prices which are \$4.75 per 100 lb. for carloads and up to \$5 for smaller lots.

Nitrate of Soda—The market is steady and business is restricted to a small volume. Quotations are unchanged at 2.17½c. per lb. for spot and futures.

Mining Stocks

New York, Dec. 30—The market on the Stock Exchange this week was rather active, considering that it was broken by a double holiday, and that another is coming. At the close the tendency is rather upward, with prices strong, notwithstanding an attempt of some large operators to bring about a general break. A few stocks sold off sharply, but most of the issues largely dealt in held firm.

On the Curb the copper stocks lead in dealing. Some of them advanced, others held their prices and only a few declined. On the whole the market was rather irregular, but with no decided weakness. Such declines as occurred at the close were due to profit taking. The Cobalt stocks were irregular, but showed a good buying demand. The Nevada gold stocks were the weakest of any deal in. For a holiday week the total volume of business was fair.

Boston, Dec. 29—The market has been on the mend, although the week has included but four days, as the Exchange was closed Christmas and the following Saturday. Prices show a material improvement and considerable activity was generated in spots, particularly in some of the Lake issues. Isle Royale was conspicuous with a \$3.02½ advance to \$26. Atlantic is up \$1.25 to \$17.02½; Centennial \$1.75 to \$33.25; Alouez \$1 to \$37.50; Franklin \$1.75 to \$17.50; Mohawk \$3.25 to \$7.25; Oseola \$5.75 to \$34.75; Quincy \$2 to \$95; Tamarack \$8.50 to \$85, the latter reacting to \$82; Wolverine \$2 to \$152. Copper Range sold up \$3.37½ to

\$82.50. Two $\frac{1}{2}$ dividends are announced by the Champion, one-half of which is owned by Copper Range and the other half by the St. Mary's Mineral Land Company.

Amalgamated has been in good demand and has risen \$4.50 during the week to \$84.62 $\frac{1}{2}$. The declaration of 50c. quarterly dividend by the Anaconda presages the usual Amalgamated dividend next month. Miami has been a feature with an advance from \$12.50 to \$15.50. Superior Copper has been neglected, compared with late activity, and is off \$1.37 $\frac{1}{2}$ to \$34. This stock was bulled pretty hard a few weeks ago. Arizona Commercial rose \$2 to \$39.50, losing half of it, and Boston Consolidated stiffened \$1.37 $\frac{1}{2}$ to \$17.

Announcement is made that a new contract has been made by the Boston Consolidated with the Garfield smelter of the American Smelters' Securities Company. Calumet & Hecla has advanced \$15 to \$169 and Calumet & Arizona touched \$175. North Butte rose \$3.37 $\frac{1}{2}$ to \$86; Old Dominion \$2.87 $\frac{1}{2}$ to \$58.62 $\frac{1}{2}$; Parrot \$1.25 to \$30; Shannon \$1.25 to \$18. Word comes of the starting of the Balaklava smelter and the renewal of regular Trinity shipments.

United States Smelting has risen \$2.25 to \$45; and Utah Consolidated \$3.37 $\frac{1}{2}$ to \$47. North Lake Mining has been taken from the Curb and put on the unlisted department of the Stock Exchange.

Curb features have been the strength of First National, and the weakness of Consolidated Arizona Smelting.

NOTE—These quotations are for ordinary wholesale lots in New York unless otherwise specified, and are generally subject to the usual trade discounts. In the cases of some of the important minerals, such as phosphate rock, pyrites, and sulphur, in which there are well established markets, the quotations fully represent the latter. But in the cases of some of the minor mineral products, the quotations represent what dealers ask of consumers and not what producers can realize in selling their outputs as matters of private contract.

Mineral and Metal Production in 1908

Statistics of the Output of the More Important Substances. Commercial Movements. Market Conditions. Mining and Metallurgy

SOME INCREASES, MANY DECREASES

In the accompanying table we summarize the production of the more important minerals and metals in the United States in 1908 so far as it has been possible to collect the statistics at so early a date. The figures for copper, lead and spelter are based on reports received directly from the producers, who have communicated their actual output during the first 11 months of the year, together with their estimates of probable production in December; in many cases the estimates are for only the last few days of December. The other statistics are based chiefly on the reports of pro-

ducers, given by the various contributors to this number and our editorial statistics. This is because the articles of our outside contributors were necessarily written and put into type before our own statistics were available, which in some cases was not until Jan. 6, 1909, and consequently the statistics of our contributors are generally estimates. This explanation will account for discrepancies, though the reason will be so obvious to our readers that an explanation is hardly required.

We thank the producers of metals and minerals for their courteous cooperation

was punctured. During the first two months of 1907 prices continued to rise, but as early as March it was manifest that industrial activity was on the downward grade. A stock of unsold copper began to accumulate in May, but it was not until after the middle of July that many prominent industrialists, who should have been better informed, awoke to the fact that a general recession in business was not merely impending, but had actually proceeded far.

The year 1908 began with the panic conditions a matter of history, but with

(a) Includes zinc-lead pigment.

ducers, State mine inspectors, and special correspondents. The statistics for the production of gold and silver in the United States are the preliminary estimates of the Director of the Mint.

Even under these conditions, it is impossible to insure accuracy. Among other difficulties, there are always likely to be duplications or omissions in the reports of the producers, which can be corrected only by careful investigation involving considerable time. However, we are confident that the statistics which we are able to present at this early date are close approximations to the truth.

It will be observed that in some cases there are differences between the statistics

by promptly and fully furnishing us with statements of their production in 1908 and we thank many other persons who have aided in the preparation of this number.

The metal industries suffered in 1908 from the general commercial depression that began in 1907. This has proved to be more far-reaching than was at first supposed. Indeed, the setback began earlier than people in general were aware, probably the threatening of adverse conditions was apparent to the great international banking houses before the end of 1906—perhaps before the Cobalt boom

demand for the metals at low ebb, as was naturally to be expected, and the accumulation of large unsold stocks, the latter being unequally distributed among the producers, although there was scarcely one who did not have something on hand. During the falling market in the last quarter of 1907, some producers sold steadily for what could be realized; others held aloof, expecting all the time a recovery, only to be obliged finally to sell at a sacrifice when necessity compelled; others who missed the market on the decline, but were able to finance their accumulations, were carrying large stocks at the beginning of 1908.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres. and Treas. ROBERT McKEAN, Sec'y.

505 Pearl St., New York.

London Office: 6 Boulevard Street, London, E. C., Eng.

Cable Address "ENGINJOUR, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

January 2..... 10,000

January 9..... 14,000

None sent free regularly, no back numbers.

Figures are free, net circulation.

Metal Markets

New York, Jan. 6.—The metal markets generally show some revival of activity at the opening of the year, but no marked changes from the previous week.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Nov. 1908..	\$ 2,967,795	\$ 2,892,225	Exp. \$ 75,570
" 1907..	615,169	63,574,871	Imp. 62,959,702
Year 1908..	73,857,749	45,105,993	Exp. 28,750,846
" 1907..	54,211,240	98,949,557	Imp. 44,738,317
Silver:			
Nov. 1908..	3,361,987	3,275,609	Exp. 86,378
" 1907..	4,187,378	3,602,405	" 584,973
Year 1908..	47,111,382	37,814,676	" 9,296,706
" 1907..	57,212,168	41,690,324	" 15,521,844

Exports of specie from New York, week ended Jan. 2: Gold, \$31,250, to the West Indies and Panama; silver, \$723,796, chiefly to London. Imports: Gold, \$77,612; silver, \$80,761, both from Central and South America.

Gold.—The London price of gold in the open market is about the same as last week, 77s. 9½d. per oz. for bars, and 76s. 5d. for American eagles.

Platinum.—Prices are strong. Dealers quote \$24.25 per oz. for ordinary metal, \$26.25 for hard, \$20@21 for good scrap.

SILVER AND STERLING EXCHANGE.

Dec.-Jan.	31	1	2	4	5	6
New York....	50½		50½	50½	50½	50½
London....	23½	23½	23½	23½	23½	23½
Sterling Ex.	4.8700		4.8710	4.8705	4.8680	4.8690

New York quotations, cents per ounce troy, fine silver; London, pence per ounce sterling silver, 0.925 fine.

Silver.—Owing to a variety of causes the tone of silver has improved, and price has advanced to 23½d. Chief among these causes are a better feeling in India owing to the uptake of silver for the interior; buying on China account; covering by speculators, and some purchases on long account by those who are hopeful of business this coming year.

Copper, Tin, Lead and Zinc

Dec.-Jan.	Copper.			Tin.	Lead.	Spelter.	
	Lake, Cts. per lb.	Electrolytic, Cts. per lb.	London, £ per ton.	Cts. per lb.	Cts. per lb.	New York, Cts. per lb.	St. Louis, Cts. per lb.
31	14½ @14½	14½ @14½	63½	29	4.15 @4.20	5.12 @5.15	4.97 @5.00
1	14½ @14½	14½ @14½			4.17 @4.22	5.15 @5.17	5.00 @5.02
2	14½ @14½	14½ @14½			4.17 @4.22	5.15 @5.17	5.00 @5.02
4	14½ @14½	14½ @14½	63½	29	4.17 @4.22	5.15 @5.17	5.00 @5.02
5	14½ @14½	14½ @14½	63½	29	4.17 @4.22	5.15 @5.17	5.00 @5.02
6	14½ @14½	14½ @14½	63½	29	4.17 @4.22	5.15 @5.17	5.00 @5.02

London quotations are per long ton (2240-lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper.—The demand to which reference was made last week continued up to the close of the year, and round quantities of both electrolytic and Lake copper were sold to foreign and domestic consumers. Since the beginning of this week a much quieter tone prevails. The market closes higher and steady at 14½@14¾c. for Lake copper; 14¼@14¾c. for electrolytic in ingots, cakes and wirebars. The average of the week for casting copper is 14@14½ cents.

Copper sheets, cold-rolled, 20c.; hot-rolled, 19c. per lb. Wire, 15¾c. base.

The London Standard market fluctuated within narrow limits and closes a fraction lower than last week, quotations being cabled at £63 15s. for spot, £64 10s. for three months.

Statistics for the second half of December show an increase in the visible supplies of 2000 tons.

Refined and manufactured sorts were quoted: English tough, 667; best selected, 666@67; strong sheets, £78@79.

Tin.—Transactions in the London market have been of small volume, but at rather steady prices. The close is somewhat softer at £131 for spot, £132 5s. for three months.

The domestic market displayed no special features. Interest among consumers is still lacking. At the close tin is offered at 28.75 cents.

Statistics for the month of December show a decrease in the visible supplies of 1200 tons.

Lead.—Demand has been somewhat better, absorbing the lots offered from Missouri and by dealers, which had been hanging over the market. The close is firm and higher at 4.17½@4.22½c., New York.

Some lime was infused into the London market, due to cables from Australia that a strike had broken out in the mines of the Broken Hill Proprietary Company. This news started an advance, the market reaching £13 7s. 6d. for Spanish lead on Monday last, but since then an easier tendency prevails and the close is lower at £13 3s. 0d. for Spanish lead, £13 6s. 3d. for English lead.

Spelter.—Demand on the part of speculators and consumers brought about considerable activity, under the influence of which a good business was transacted at advancing prices. The close is firm at 5.15@5.20c. New York, 5@5.05c. St. Louis.

Reports from Europe are also more encouraging and the close is cabled at £21 5s. for good ordinaries, £21 10s. for specials.

Gold, Silver and Platinum in 1908

Review of the Influences and the Commercial Conditions Which Governed the Production and Price of the Three Precious Metals

WORLD'S GOLD PRODUCTION \$436,222,000

The gold mines of the world in 1908 not only kept up the great production of recent years, but increased it by a considerable amount. In the accompanying table is given the approximate production for the year, comparison being made with the ascertained figures for 1907. Some corrections will, of course, be required when the final returns are received; but the necessary estimates have been made on a conservative basis, and it is not believed that any important changes will have to be made in the total.

* GOLD PRODUCTION OF THE WORLD.

(IN DOLLARS.)

	1907.	1908.
United States.....	\$90,135,700	\$96,313,000
Transvaal.....	133,357,281	145,500,000
Australasia.....	75,819,349	74,296,000
Russia.....	26,578,253	27,500,000
Mexico.....	17,820,000	18,750,000
Canada.....	8,261,763	9,350,000
Rhodesia.....	11,266,845	13,288,000
British India.....	10,857,680	10,925,000
West Africa.....	5,627,970	5,800,000
China, Japan and Korea.....	10,402,378	10,500,000
Other countries.....	23,336,836	24,000,000
Total.....	\$413,793,125	\$436,222,000

The figures given in the table above for the United States are the preliminary statement of the director of the Mint. For nearly all the important producing countries—the Transvaal, Australia, Rhodesia, India and others—we have reports covering 11 months of the year, from which it is possible to estimate the December returns very closely. For Russia we are dependent, owing to the slowness of official action in that country, upon incomplete and partial returns, which indicate a considerable gain. Mexico, also, is estimated from partial returns.

The total increase in 1908, as compared with 1907, was \$22,428,125, or 5.4 per cent. The total gold production for 10 years past has been as follows, showing continuous gains, except in the years of the Boer war:

1899 ..	\$311,505,497	1904 ..	\$349,088,293
1900 ..	258,829,703	1905 ..	378,411,754
1901 ..	260,877,429	1906 ..	405,060,969
1902 ..	298,812,493	1907 ..	413,793,125
1903 ..	329,475,401	1908 ..	436,222,000

The gains in 1908, in the order of their importance, were from the Transvaal, the United States, Canada, Russia, Rhodesia and Mexico. Australasia alone of the large producers showed a decrease.

Gold and Silver Production in the United States

By FREDERICK HOBART.

There was a marked contrast in 1908 between the course of gold production and that of silver in the United States, the chief causes of which are briefly explained in the following pages.

GOLD PRODUCTION

Gold production in 1908 exceeded that of 1907 by 6.5 per cent., and was the greatest ever reported in a single year, notwithstanding decreases in some of the leading States. The increase over 1906, heretofore the year of greatest production, was \$1,939,455, or 2.1 per cent. In the following table is given the production by States, as estimated by Frank A. Leach, director of the United States Mint, from the returns of the various branch mints and assay offices. These figures will approximate closely the final returns, though there may be a slight readjustment as among the different States. The figures give the value of the output in dollars:

GOLD PRODUCTION OF THE UNITED STATES.

(IN VALUES.)

	1907.	1908.	Changes.
Alabama.....	\$27,400	\$43,686 L.	\$16,286
Alaska.....	18,489,400	20,930,784 L.	2,441,384

New Hampshire.....	2,306	2,306	0
New Mexico.....	330,000	240,756 D.	89,244
North Carolina.....	78,700	85,314 L.	6,614
Oregon.....	1,122,200	1,119,528 D.	102,672
South Carolina.....	58,100	58,336 L.	236
South Dakota.....	4,138,200	7,690,294 L.	3,552,094
Tennessee.....	3,800	3,186 D.	614
Texas.....	1,000	545 D.	455
Utah.....	5,121,600	3,930,290 D.	1,191,310
Virginia.....	8,300	4,321 D.	3,979
Washington.....	262,300	222,189 D.	40,111
Wyoming.....	9,400	1,773 D.	7,627
Other States.....	19,936	19,936	0
Total.....	\$90,369,800	\$96,005,906 L.	\$5,636,106
Porto Rico.....	1,200	642 D.	558
Philippines.....	64,700	306,708 L.	242,008
Total.....	\$90,435,700	\$96,313,256 L.	\$5,877,556

The lowest point touched in gold production, since the California discoveries began to have their effect, was \$30,800,000 in 1884. For eight years after that time there were fluctuations from year to year, but no great increases until 1893, when

the upward movement began which has culminated in the present large production. The total output of the United States for 16 years past has been reported as follows:

GOLD PRODUCTION FOR 16 YEARS.

1893 ..	\$35,955,000	1901 ..	\$78,666,700
1894 ..	39,500,000	1902 ..	80,000,000
1895 ..	46,610,000	1903 ..	73,591,700
1896 ..	53,088,000	1904 ..	80,723,200
1897 ..	57,363,000	1905 ..	88,180,700
1898 ..	64,403,000	1906 ..	91,373,800
1899 ..	71,053,000	1907 ..	90,435,700
1900 ..	79,171,000	1908 ..	96,313,000

The main factors in the growth of the production here shown have been the new discoveries in Alaska and Nevada; the exploitation of the Cripple Creek and other camps in Colorado; the improvements in metallurgy which have resulted in closer saving and the extended working of lower grade ores; and the improvements in handling material which have made possible the working on a large scale of low-grade placer ground, as in the dredge-worked fields of California. It is difficult to say which of these factors is the most important; all of them have contributed materially to the gain in the output of gold, which is now more than three times as great as it was 20 years ago.

If we examine the table of 1908 production we find that six States produced over \$5,000,000 each in 1907 or 1908, and from these there came in the latter year 90.4 per cent. of the total production. These States, classed in their order as producers in 1908, were:

	1907.	1908.
Colorado.....	\$20,897,600	\$22,811,784
Alaska.....	18,489,400	20,930,784
California.....	18,853,500	19,581,570
Nevada.....	15,411,000	12,090,218
South Dakota.....	4,138,200	7,690,294
Utah.....	5,121,600	3,930,290
Total.....	\$80,911,300	\$87,034,940

Four other States—Montana, Arizona, Idaho and Oregon—produced over \$1,000,000 each in 1908; no other State reached a total as high as \$250,000. In all 98.9 per cent. of the gold production was from States, or Territories, all of them in the Rocky Mountain region or on the Pacific Coast. The Southern States, our oldest gold producers, made a very small showing, notwithstanding efforts made to revive some of the old mines in Alabama and North Carolina. In our foreign possessions Porto Rico reports only a trifling output; that of the Philippines showed a large increase, though the total is still small. That it is increasing proves that attention paid to the mineral resources of the Islands is beginning to produce substantial results.

SILVER PRODUCTION

Silver production in the United States in 1908 was the smallest reported in nearly 20 years, and was less than that of 1907 by 8.3 per cent. in quantity. The decrease in values is much greater—25.8 per cent.—as the average market price of silver in New York, on which the commercial values are calculated, fell from 65.327 cents per ounce in 1907 to 52.864 cents in 1908. As usual, the production of silver was affected by that of lead and copper, in connection with which metals most of the silver is won. The production for two years, as estimated by the director of the mint, is shown in the following table in ounces of fine silver:

SILVER PRODUCTION IN THE UNITED STATES.

(FINE OUNCES.)			
1907.	1908.		Changes.
Alaska.....	179,250	201,988	I. 22,738

Total.....	56,514,700	51,798,053	D. 4,716,647
Commercial value.....	\$36,919,358	\$27,382,523	D.\$9,536,835

Three of the important silver producers—Montana, Nevada and Arizona—show gains, only that of Nevada being large. These increases were due to the greater output of copper carrying some silver. On the other hand there were heavy decreases in three important States—Colorado, Idaho and Utah. Idaho and Colorado are the largest silver-lead producers; in Utah the loss resulted largely from the smelter troubles, to which reference was made under gold production.

As above noted, the silver output of 1908 was the smallest reported for 20 years, with the single exception of the year 1894. The production for 20 years past has been, in fine ounces:

SILVER PRODUCTION FOR 20 YEARS.

1889.....	50,000,773	1899.....	54,764,000
1890.....	54,516,300	1900.....	57,647,000

1898.....	51,438,000	1908.....	51,798,053

It is not possible to analyze the underlying causes directly affecting the variations in the production of silver.

The Commercial Movement of Gold and Silver

BY FREDERICK HOBART

The great production of gold as shown in the preceding columns, still continued in 1908. Its movement exercises a most important influence upon the commerce of the world; but in its turn is directed and influenced by the currents of that commerce. That the production of gold was not only maintained, but increased, did not prevent the occurrence of a year of general depression; though it served in some degree to mitigate the effects of that depression. The supply of gold, however, is one of the complexity of causes which affect and direct the commerce of the world, any discussion of which is impossible here.

The movement of silver, while far less important than that of gold, still has its place in commerce of sufficient importance to be carefully recorded.

COMMERCIAL MOVEMENT OF GOLD

The additions made to the world's visible stock of gold during 1908 amount in round figures to about \$340,000,000, or about 75 per cent. of the total production during the year. This is, in all probability, the largest proportion of the production which has ever taken form and become a part of the world's circulating medium. That it did not prevent a depression which extended, in a greater or less degree, to all the commercial nations of the world is a remarkable fact. It was not sufficient to make up for the great absorption of capital which had been going on for several years previously.

GOLD MOVEMENT IN THE UNITED STATES

The gold movement in the United States for 11 months ended Nov. 31 was as follows:

	1907.	1908.
Exports.....	\$54,211,240	\$73,867,749
Imports.....	98,949,557	45,105,993
Excess.....	Imp.\$44,738,317	Exp.\$28,751,756

The statement for the full year, 1907, showed a total of imports amounting to \$88,182,385. The movement for December, so far as reported, indicates that for 1908 there was a total of about \$36,000,000 excess of exports. The imports in 1907 were swelled by the large amounts borrowed from European bankers in November and December to tide over the panic period; in 1908, toward the latter part of the year, it became necessary to repay in gold a part of these advances which had not been met by shipments of merchandise or transfers of securities. So far as can be estimated, the debt is not yet fully settled.

GOLD MOVEMENT IN GREAT BRITAIN

The movement of gold in Great Britain for 11 months ended Nov. 30 is reported as follows:

	1907.	1908.
Imports.....	£40,506,000	£41,539,849
Exports.....	45,086,743	45,197,922
Excess.....	Imp.£ 3,619,866	Exp.£ 3,658,060

Great Britain has, therefore, been placed in the very unusual position of showing an excess of gold exports. This was largely due to the extraordinary demands from France, which appears just now to be the universal creditor. A decrease in the export trade in many staple products also had its influence.

GOLD MOVEMENT IN FRANCE

The gold movement in France is reported up to date for only 10 months of the year, the figures being as follows:

	1907.	1908.
Imports.....	Fr. 389,243,000	Fr. 789,825,000
Exports.....	94,000,000	18,547,000
Excess, imports.....	Fr. 295,239,000	Fr. 771,478,000

France has been steadily accumulating gold throughout the year, the policy of its leading bankers having been, apparently, to draw gold from every possible source in order to secure their reserves against all possible financial and political contingencies.

BANK GOLD HOLDINGS

The gold holdings of the great European banks in the closing weeks of 1907 and 1908 compare as follows, the amounts being reduced to dollars:

	1907.	1908.	Changes.
England.....	\$168,383,445	\$168,067,430	D. \$296,215
France.....	538,787,750	669,929,635	I. 131,141,885
Germany.....	137,140,000	124,155,000	D. 12,985,000
Aust.-Hun.....	228,750,000	244,860,000	I. 16,100,000
Russia.....	607,125,000	606,806,000	D. 319,000
Netherl'ds.....	38,239,100	41,993,000	I. 3,753,900
Belgium.....	17,610,000	20,103,335	I. 2,493,335
Italy.....	193,520,000	187,000,000	D. 6,520,000
Spain.....	78,210,000	78,965,000	I. 755,000
Sweden.....	20,925,000	21,215,000	I. 290,000
Norway.....	8,255,000	8,260,000	D. 5,000
Switzerland.....	13,735,000	23,495,000	I. 9,760,000
Total.....	\$2,046,925,505	\$2,279,748,380	I. \$232,822,785

The specie held by the associated New York banks in the last week of 1907 was \$181,503,100; in the last week of 1908 it was \$272,248,200, showing a large increase. This surplus includes silver coin as well as gold. The banks have materially strengthened their reserves as compared to a year ago; but these specie holdings were diminished by some \$35,000,000 during the month of December.

The United States Treasury held on Dec. 1 a total of \$188,483,313 available gold coin and bullion; besides this it held \$850,817,809 deposited to secure gold notes outstanding and the so-called circulation reserve of \$150,000,000; making a total accumulation of \$1,189,301,122 in gold—the largest quantity ever gathered in one place. The amount of gold in circulation in the United States—including gold reserves held by banks—is estimated by the Treasury Department at \$610,060,000; but it is believed that this estimate is too high, and that insufficient deductions have been made for losses, destruction by fire and other accidents, gold sent

out of the country and not reported, and other causes.

Deducting the excess of exports from the production of the year, the increase of the gold supply of the United States in 1908 was approximately \$67,560,000. From this is again to be deducted the quantity used in the arts and otherwise absorbed or lost. Assuming the same ratio as for the world's general supply, the gold monetized or made available for the uses of commerce and trade in 1908 was approximately \$50,500,000, an amount not much more than one-fourth of that which this country absorbed in 1907. At the present time it appears probable that the same conditions will extend through at least the earlier part of the new year.

It is probable that, as usual in time of depression, the quantity of gold absorbed and used in the arts decreased considerably during the year, not only in the United States, but also in Europe. The definite determination of this quantity is impossible at all times, even when accounts are summed up over a series of years, and it has always been more or less a matter of conjecture.

COMMERCIAL MOVEMENT OF SILVER

The movement of silver, while almost as great in quantity as in the previous year, was represented by lower values, owing to the steady decrease in prices. The exports and imports of silver in the United States for the 11 months ended Nov. 30 were as follows in value:

SILVER MOVEMENT IN THE UNITED STATES.

	1907.	1908.	Changes.
Exports	\$57,212,168	\$47,111,382	D. \$10,100,786
Imports	\$1,690,324	\$7,814,676	D. 3,875,748

Net import, \$15,521,844 D. \$ 9,296,706 D. \$ 6,225,138

At the average values of the year the net exports in 1907 were approximately 23,760,000 oz., and 17,586,000 oz. in 1908; the decrease in quantity being 6,174,000 oz., or 26 per cent., while the decrease in values was 40.1 per cent.

Only a small proportion of the total exports—about \$4,500,000 in 1908—went directly to the East, being shipped from San Francisco to Hongkong. The balance went chiefly to Europe, the greater part of it to the central market in London.

SILVER MOVEMENT IN GREAT BRITAIN.

The silver movement in Great Britain for 11 months ended Nov. 30 was as follows, in values:

SILVER MOVEMENT IN GREAT BRITAIN.

	1907.	1908.	Changes.
Exports	\$15,813,329	\$11,964,119	D. \$4,000,210
Imports	\$2,667,024	\$9,868,812	D. 5,797,212

Excess, exp. £ 1,146,305 £ 2,215,307 D. £1,069,002

Here again the decrease in values was much greater than that in quantities, owing to the lower prices. A special statement of the exports to the Far East from Great Britain is as follows, complete to Dec. 17, or within two weeks of the end of the year:

SILVER EXPORTS FROM LONDON TO THE EAST.

	1907.	1908.	Changes.
India	£10,531,354	£8,412,390	D. £2,118,964
China	417,350	641,400	I. 224,050
Straits	691,150	164,885	D. 526,265
Total	£11,639,854	£9,218,675	D. £2,421,179

The decrease in values here shown was 20.8 per cent. Owing to the lower prices, however, the fall in quantities was small, the total value above representing approximately 92,538,000 oz. in 1907, and 90,668,000 oz. in 1908, a decrease of only 1,970,000 oz., or 2.1 per cent.

From this table it appears that India has taken at least the same quantity of silver as in 1907, but there has been a large decrease in other Eastern countries. The Straits are practically out of the market, and have been so since the currency changes made in that British dependency two years ago. China took some quantities early in the year, but since then has been a seller, not a buyer, disposing of the surplus metal taken two years ago, chiefly in India, but occasionally in London.

PRICE OF SILVER

The price of silver showed a steady decline, almost uninterrupted, during the year. The following table shows the monthly averages of the quotations in London and New York for two years:

AVERAGE PRICES OF SILVER.

Month.	New York.		London.	
	1907.	1908.	1907.	1908.
January	68.673	55.678	31.789	25.738
February	68.833	56.090	31.852	25.835
March	67.519	55.365	31.325	25.570
April	65.462	54.505	30.253	25.183
May	65.971	52.798	30.471	24.877
June	67.090	53.663	30.893	24.760
July	68.144	53.115	31.366	24.514
August	68.745	51.683	31.637	23.858
September	67.792	51.720	31.313	23.877
October	62.435	51.431	28.869	23.725
November	58.677	49.647	27.164	22.933
December	54.665	48.709	25.362	22.493
Year	66.327	52.864	30.188	24.402

New York, cents per fine ounce; London, pence per standard ounce.

The average yearly quotation of silver in New York for 10 years past has been as follows in cents per fine ounce:

1903	50.580	1904	57.221
1905	61.330	1906	60.352
1907	58.950	1908	66.701
1909	62.160	1907	57.327
1905	52.570	1908	52.869

The average for 1908 was lower than in seven out of the 10 years included in the table.

The fall in prices, which reached the lowest point since 1902, was due, apparently, in part only to the lower demand from the East. The increase in supplies from Canada and Australia was another cause. There were also minor contributing factors. The demand for silver for use in the arts has been small, in consequence of the general condition of business. The United States Mint was not a buyer from early in the year till late in December. European mints, except the French mint, took less than the usual

quantities. While of less importance than the trade with the East, these factors have had their effect.

Another point to be considered was the existence for several months of an extensive bear operation in London, ably directed by some large Chinese and Indian houses. Any movement for an advance was checked by offers of silver on Chinese account, by statements of large shipments from China direct to India, and by reports of large accumulations of unsold metal in India. This bear movement, it is believed, is almost at an end.

UNITED STATES MINT PURCHASES

Purchase of silver by the United States Mint, for purposes of subsidiary coinage, were much smaller in 1908 than in 1907, when 14,776,500 oz. were taken. In 1908, up to April 30, these purchases amounted to 4,978,300 oz. at prices varying from 58.067 down to 54.612c., the average price paid being 55.723c. From April the mint was out of the market until late in December, when it purchased 125,000 oz. at 49.118c. delivered. The total silver bought was only about one-third of that taken in the preceding year.

Platinum

The imports of platinum into the United States for the 11 months ended Nov. 30 were 68,712 oz. in 1907, and 38,857 oz. in 1908; a decrease of 29,855 oz. This indicates a large decline in demand, as was to be expected from the general depression of business. It must be noted that a large part of the platinum sold is not consumed in the ordinary sense of the word, but returns to dealers in the form of scrap, practically uninjured, and ready for use as new metal.

At the close of 1907 refined platinum was quoted in New York at \$20 per oz.; during that year it had been as high as \$38. During 1908 the price receded from \$26 to about \$22 in July. For two or three months the market was disturbed by offers of the metal at \$18 and even as low as \$17; the source of these offers, or at least of the supply of metal, being involved in some mystery. These offers gradually ceased, and in November and December of the year prices recovered. At the close of the year dealers quote \$23@23.50 for refined platinum; \$26@26.50 for hard, which contains some iridium; and \$20@22 for good scrap.

The market for Russian platinum is controlled by a syndicate of Paris and London speculators, whose usual course is to depress prices, make long contracts with the Ural producers, and then exact from consumers all they will pay. This course is made possible by the limited quantity of the output, and the fact that there is no substitute for the metal known, in most of its uses.

The Copper Production of North America

The Production of the United States was 952,395,477 Pounds; of Mexico, 84,159,000 Pounds; of Canada, 53,494,202 Pounds

DECREASE IN REFINERY PRODUCTION

The production of copper in the United States in 1908 is given in Table I. These statistics are compiled in the same way as those for 1907, which for the first time stated the production upon the uniform basis of output of Michigan mines plus fine copper content of blister copper. The statistics for 1908 are computed from reports of all the producers, with a few insignificant exceptions, who have stated their actual production for the first 11 months with their own estimates for December. The reports having been received in most cases after the middle of the month and in some cases after the close of the year the estimates are probably close. However, some large smelters frequently make clean-ups at the end of the year that turn out larger or smaller than expected, and even in the possession of the complete data for computing copper production there are numerous items whereof the

I. PRODUCTION OF COPPER.

Group.	1907.	1908.
Michigan mines	220,317,041	221,500,000
Smelters in Arizona and Texas.	262,597,624	293,365,977
Smelters in Montana and Wyoming.	229,362,164	238,102,000
Smelters in Utah and Nevada.	90,100,052	81,051,799
Smelters on Pacific Coast (a).	21,936,026	40,698,720
Smelters in Mississippi Valley.	24,062,550	24,019,355
Smelters on Atlantic Coast (a).	13,640,930	15,190,847
Smelters in Tennessee.	14,784,379	14,750,000
Miscellaneous (b).	2,441,000	3,716,779
Totals.	879,241,766	952,395,477

(a) These statistics do not measure the relative importance of these groups of smelters which produce much copper from foreign ore. (b) Includes exports of ore and matte and copper produced by lead desilverizers.

II. PRODUCTION OF COPPER BY STATES.

State.	1907.	1908.
Alaska	6,610,680	5,311,600
Arizona	236,866,761	288,885,644
California	33,308,823	37,520,067
Colorado.	13,344,118	15,042,312
Idaho.	11,471,101	9,125,797
Michigan	220,317,041	221,500,000
Montana	226,290,873	255,446,447
Nevada	1,462,450	11,362,638
New Mexico	8,652,873	5,737,505
Utah	65,333,115	75,298,906
Wyoming	2,919,137	2,551,468
South and East (a).	22,408,606	20,182,328
Other States (b)	6,166,098	4,421,825
Total	879,241,766	952,395,477

(a) Includes Vermont, New Hampshire, Pennsylvania, Virginia, North Carolina, Alabama and Tennessee. (b) Includes Washington, Oregon, South Dakota, Texas, and the production of the lead desilverizers and others which it is impossible to distribute according to place of origin.

III. CONSUMPTION OF COPPER. (a)

	1907.	1908.
Stock Jan. 1.	9,000,000	120,000,000
Imports of refined.	5,000,000	None
Production.	1,152,747,890	1,105,000,000
Total supply.	1,166,747,890	1,225,000,000
Exports.	508,929,401	664,000,000
Remaining in U. S.	657,818,489	561,000,000
Stock Dec. 31.	120,000,000	(b)
Delivered for consumption.	537,818,489	(b)

(a) The figures for 1908 in this table are estimates, and are to be taken only as an attempt at a generalization. The stock of refined copper Jan. 1, 1908, is well established. As for the production, we take the American output of blister and Lake copper (952,000,000 lb.), plus the imports (212,000,000 lb.), plus 20,000,000 lb. for copper remelted from scrap and junk, the last being a guess based only upon the production in 1907. (It is well known that much less of this material is reclaimed at low than at high prices.) From the total of 1,184,000,000 lb. it is necessary to deduct 10,000,000 for copper marketed as bluestone, and 9,000,000 lb. for ore and matte, included in the United States production, which was exported to Mexico and Canada and figures again in the imports from those countries. We make a further deduction of 60,000,000 lb. for blister copper included in the statistics of production and imports that could not have been turned out as refined before the end of 1908. This leaves 761,000,000 as available for consumption in the United States. The separation of this into consumption and stock is uncertain. There has been an idea in the trade that the domestic consumption has been smaller than in 1907, which has probably been the case, but there are no authoritative statistics upon this subject nor upon the amount of stock on hand. (b) No reliable data available.

entry or rejection is necessarily a matter of opinion, wherefore the final report will doubtless show a difference of perhaps 1 per cent. from this preliminary report.

The allocation of the production among the States and Territories can never be made with precision; that being so in the case of the final statistics, the distribution at this early date is necessarily less perfect. So far as possible we have made a distribution in Table II. The figures for Arizona, Michigan and Montana are probably close; those for California, Nevada and Utah will undergo more revision, California and Nevada probably to gain at the expense of Utah.

We made no attempt to collect statistics of the production of refined copper at this early date. The total is doubtless less than in 1907. At the beginning of 1908 the refineries were just feeling the curtailment begun at the mines 60 to 90 days earlier. At the end of 1908 they were not yet turning out the big output of Washoe, Cananea and Steptoe in November and December. Basing our estimates on such data, together with the production and importation of blister copper, we

compute the production of refined and amount available for consumption in Table III.

Production of Copper in Mexico

On the basis of the net imports into the United States plus the Boleo production, the copper production of Mexico in 1907 was 126,710,000 lb. Figuring in the same way, the production in 1908 was 84,159,000 lb. Our reports from nine smelting works, producing blister from Mexican material, give 85,476,763. Boleo and Moctezuma increased their production, but not enough to offset the decrease from Cananea, which was idle during the major part of the year and Teziutlan, idle throughout the year. Operations are now in full swing again at Cananea, the new concentrator at Moctezuma is working, and the new smelter at Teziutlan is to be blown in during February, 1909. Boleo was the largest producer in Mexico in 1908; Aguascalientes next, and Cananea third.

Production of Copper in Canada

The copper production in the Dominion, computed from direct reports from all of the producers was 53,494,202 lb. in 1908, compared to 46,356,382 lb. in 1907. The production in 1908 by districts was approximately as follows:

Boundary.	26,361,483
Rossland.	5,538,207
Coast.	1,849,473
Ontario and Quebec.	19,612,243
Nova Scotia.	122,000
Miscellaneous.	10,796
Total.	53,494,202

The above statistics are computed on the basis of blister copper reported. Several smelters producing matte in Canada reported matte shipments in excess of the blister reported by the concerns converting their product, the difference being explained, of course, by material in transit and accumulated in stock.

The Copper Market at New York

The severe financial depression which culminated in the fall of 1907 had a highly disturbing influence on all industries, but especially on those that are the principal users of copper. Money became exceedingly scarce, interest rates in consequence very high, and the uncertainty

as to the future did not tend to encourage large commitments on the part of the great financial institutions in this country. The railroads, our chief consumers, were particularly affected by

such conditions, which in their case were further aggravated by hostile legislation in a great many States, directed toward a regulation of freight and passenger rates. Improvements under way were

stopped and plans for further extensions abandoned.

All this, and similarly unfavorable conditions in other industries, naturally affected to a large extent the consumption

of copper, so that an accumulation of approximately 120,000,000 lb. of refined at the beginning of the year was sold. Production on all sides was curtailed.

Fortunately, much better conditions existed in Europe as far as consumption of copper was concerned, and exports from this side reached record-breaking proportions. These and a gradual improvement in consumption in this country disposed of a large part of the accumulated stocks and current production by early spring. By this time, money became more plentiful and rates of interest were once more on a normal level, so that home consumers, who had all along been most conservative and in buying had covered their immediate requirements only, began to show some interest in purchases for future delivery, something they had not done for almost a year. However, by the middle of the year there was again an accumulation of unsold stock.

Late in the summer, production was in full swing, and while the old camps had resumed normal operations, the new producers in Nevada and Utah also made themselves felt. In the Fall, when it became apparent that a Republican victory at the Presidential election was assured, buying of copper among consumers became general and requirements up to the end of the year were covered. These purchases and continued large exports to Europe took care of current production.

The outlook for copper is fairly favorable. The market is not burdened with an enormous stock, that in this country being no larger than at the beginning of the year, while that in Europe, although much larger than for some years past, is not any bigger than was considered the normal supply at a period when production of copper was only about one-half of what it is now. On the other hand, consumers have not anticipated their wants and will have to replenish their stocks of copper whenever new business is entertained by them.

The year 1908 opened with prices ruling at about 13 $\frac{1}{4}$ ¢ for Lake copper and 13 $\frac{1}{2}$ ¢ for electrolytic. During January, there was an entire absence of demand on the part of domestic consumers. Europe, however, continued a large buyer and thus sustained prices, which at the end of the month had advanced to 13 $\frac{3}{4}$ ¢ for Lake and 13 $\frac{3}{8}$ ¢ for electrolytic.

In February it developed that for the time being European buyers were satisfied, and an effort was made by American holders to induce fresh purchases through a reduction in prices, which gradually established quotations at the end of the month on basis of 12 $\frac{7}{8}$ ¢ for Lake and 12 $\frac{5}{8}$ ¢ for electrolytic. These low prices had the desired effect, and the Chinese, who are always alert to any undue depression in the price of copper

also became buyers to a moderate extent. The demand thus created, however, was not of long duration, and by the first part of March quotations stood at 12 $\frac{1}{2}$ ¢ for Lake and 12 $\frac{1}{4}$ ¢ for electrolytic. Domestic consumers at that time took hold of the market, so that a steady improvement set in and prices advanced at the end of the month to 13 $\frac{1}{4}$ ¢ for Lake and 13¢ for electrolytic.

Prices remained on about this level during April, when fairly large quantities were purchased by home consumers for nearby delivery to take care of orders booked by them. Interest was also evinced in purchases for more distant delivery.

In May, fairly large quantities of copper were pressed on the market by Japanese holders, owing to a severe financial crisis then existing in the Far East, and tended to unsettle prices, which declined toward the middle of the month to 12 $\frac{3}{4}$ ¢ for Lake and 12 $\frac{1}{2}$ ¢ for electrolytic. At the end of the month, some improvement was again noticeable, brought about by the more confident feeling shown in the stock exchanges of the world, and quotations were established at 12 $\frac{3}{4}$ ¢ for Lake and 12 $\frac{5}{8}$ ¢ for electrolytic.

In June, activity continued to a moderate degree, and prices practically remained unchanged. By this time a slow but gradual improvement had manifested itself in the more important copper-consuming industries. For instance, the wire industry, which during January had stood at 25 per cent. of the normal capacity, showed an increase in February to 33 per cent., March 40 per cent., April 50 per cent. and May-June 60 per cent.

This improvement made still further progress in July and both domestic and foreign consumers were buyers of large quantities of copper. In consequence of these transactions, prices advanced during August to 13 $\frac{3}{8}$ ¢ for Lake and 13 $\frac{3}{4}$ ¢ for electrolytic. A disturbing influence toward the second half of that month were offerings of copper held by speculators, which lots, however, were readily

picked up by consumers at a discount from prices quoted by first hands.

After the great activity during the preceding two months, a reaction was to be expected, and occurred during September. First hands were, thanks to the large sales made, in a comfortable position, and did not press on the market. Sundry small lots of second-hand copper, however, were offered and made themselves disturbingly felt. Prices declined steadily, and at the end of September closed at 13 $\frac{1}{8}$ ¢ for Lake and 13 $\frac{1}{4}$ ¢ for electrolytic.

The approaching elections had a restricting influence on buyers during the first half of October. The feeling as to the outcome of the elections became more hopeful during the second half of October and influenced by a cheerful tone on the stock exchange, which inspired confidence, buyers took hold of the market in earnest. Enormous quantities of copper were purchased during the last 10 days of October and immediately after the election of Mr. Taft, so that prices advanced by leaps and bounds and on November 10 reached a basis of 14 $\frac{3}{4}$ ¢ for Lake and 14 $\frac{3}{8}$ ¢ for electrolytic. The activity of the market, however, received a check during the second half of November, when the demand subsided and when copper bought by speculators during the advance was realized upon. While necessarily under these conditions prices had to decline somewhat from the high level, many of the first hands showed no disposition to enter the market, having practically disposed of all the copper that they expected to have available up to the end of the year. The undertone, therefore, remained sound and prices steady at a level of 14 $\frac{1}{4}$ ¢ to 14 $\frac{1}{8}$ ¢ for Lake and 14¢ to 14 $\frac{1}{4}$ ¢ for electrolytic. These conditions lasted nearly to the end of December, the holiday season always exercising a check upon business, but at the end the market started upward, the year closing with 14 $\frac{1}{2}$ ¢ for Lake and 14 $\frac{1}{8}$ ¢ for electrolytic.

Copper in Arizona

By JAMES DOUGLAS*

The financial gloom with which the past year opened did not acutely affect the large copper mines of Arizona, if we may judge by their activity. The Verde ran continuously and produced its normal output. In the south the Warren district increased rather than diminished its contribution, and the Clifton witnessed no falling off.

In Arizona's neighbor, Sonora, the Greene-Cananea Company, which shut down in October of 1907, resumed work

*President, Phelps, Dodge & Company, 93 John street, New York.

New York, cents per pound. Electrolytic is for cakes, ingots or wirebars. London, pounds sterling, per long ton, standard copper.

in September of 1908, under the management of Dr. L. D. Ricketts. The concentrating plant, which had been built from designs by Doctor Ricketts during the previous administration, underwent no change. But the furnace and converting plants were completely rebuilt on the old site; the reverberatory was remodeled advantageously, in both its smelting and steam-generating qualities; the bedding and conveying devices, which had been planned by Arthur S. Dwight and the Robins company, were put into working order, and justified the economical results which were claimed for them. Notable saving in cost of smelting resulted, and all and more than was expected has been realized from the introduction of the caving and milling system in the mines. This great property has resumed work with every probability of attaining success, despite the enormous capital with which it is overburdened. C. F. Shelby has, in the JOURNAL, described with such candor and fullness of detail most of the improvements introduced in his smelting department so that outside testimony would be superfluous.

At Nacozari the old mill was put, perhaps only temporarily, out of commission, and the new mill of 2000 tons capacity is treating 1500 tons of Pilares ore a day. The concentrates are still shipped for metallurgical treatment to Douglas, and yield in copper about 2,000,000 lb. a month. The economies obtained at Cananea in the reverberatory smelting, with oil as fuel, of concentrates and flue dust, revived the discussion of the wisdom of the resumption of smelting at Nacozari. In addition to discarding the old concentrator, the gas plant and gas engines have been supplanted by a large power plant in which Curtis engines are used to operate the generators. The wood gas and gas engines were not rejected on account of dissatisfaction with cost, but the size of the new transmission plant required for moving the new mill, and supplying the necessary power to the mines would have demanded a cumbersome equipment of gas engines. Accurate estimates of cost of a horsepower under the two systems have not yet been made.

BISBEE AND DOUGLAS

At Bisbee preparations have almost been completed to hoist by a skip ore from every section of the mine through the new Sacramento shaft; then to load a train of cars by a belt and tripper and by this means to secure a uniform mixture. In the central power house, situated near the Sacramento shaft, power is derived from Curtis turbines, and is distributed for underground haulage by electric current and by compressed air to the engines of the old shafts, which will be used only for the hoisting of timber and of men.

At Douglas the Calumet & Arizona works were not only enlarged, but also

rearranged to meet the increased demands made on them by the production of the Superior & Pittsburg mines. At the Copper Queen Douglas reduction works the shipment of about 300 tons of concentrates a day from Nacozari, necessitates a modification of both method and plant. Experiments are under way to determine whether sintering or reverberatory smelting will be used as a supplement to the blast-furnace practice.

Nothing of note occurred in the Clifton district, but the output of all the three smelting companies shows an increase.

OTHER DISTRICTS

In the Warren district the Copper Queen produced less than in 1907, and the joint mines of the Calumet & Arizona and Superior & Pittsburg much more than in 1907. The result of the mining in the Warren and Clifton districts will probably show an increase for 1908 over 1907 of approximately two and a half million pounds.

The Imperial company erected a second furnace and contemplates the building of a third. Saddle Mountain, Twin Butte, Helvetia and most of the smaller mines, have not resumed operations, or are working in a very languid way.

The Old Dominion furnaces exceeded their 1907 output by about 940,729 lb., and of the total output about 30,560,832 lb. came from the company's own mines. The development of the Miami mine and the success in floating that company gave a great impulse to both mining and smelting in that territory; but last year none of the companies except the Old Dominion was a large producer.

The closure of the smelter on the Agua Fria continues to impede general copper mining in Yavapai county.

During the year 1908 a new district loomed up as a possible large producer. As far back as the prosperous Tombstone days the Turquoise district, situated in the foothills of the Dragoons where they sink into the Sulphur Spring valley, attracted much attention on account of its silver mines. They were said to have been abandoned on account of the refractory character of the ore and the presence of copper. Nearly there has, of late, been opened in what is known as the Courtland district, by the Calumet & Arizona Company and by the Great Western Mining Company, a most promising bed of copper carbonate in a manganese gangue. The deposit is in limestone cut by intrusive rocks, and the geological conditions, as well as the actual developments promise well. The year, 1909, will determine whether another notable district will add to the already large production of the Territory. If so, it will maintain its supremacy for all of the running mines; unless overtaken by accidents or unfavorable general conditions, will maintain to the full their present output, and some, such as those of the Calumet & Arizona and

Old Dominion companies, will probably show an increase. The low-grade mines of Gila county, notably the Miami, may contribute something to the year's total, but it will not be much, as the Miami mill will not be running till 1909 is nearly drawing to a close.

PRODUCTION OF THE YEAR

Under the tax law passed by the legislature of Arizona in 1907, the gross product of the mines and mining claims is taxed, and, therefore, the tax statement gives besides the quantity, the actual gross value of the copper, gold and silver extracted from the minerals mined in the Territory. The law was passed in 1907, but was effective for taxes due for 1906. The returns are, therefore, available for 1906 and 1907.

The number of companies taxed in 1906 was 62, which was increased to 80 in 1907.

The total quantity and value assessed in 1906 was: Copper, 255,012,155 lb.; gold, 125,016 oz.; silver, 2,704,044 oz., with a total gross value of \$53,801,781. In 1907 the figures were: Copper, 253,784,698 lb.; gold, 118,374 oz.; silver, 2,423,723 oz., with a total gross value of \$54,788,074.

In both years the Copper Queen heads the list of gross value of product with \$14,236,428 in 1906, and \$13,699,107 in 1907. In 1906 and 1907 the United Verde comes next with \$8,038,126 and \$7,066,126. The Calumet & Arizona follows with \$7,337,748 in 1906, and \$6,226,664 in 1907. The Arizona Copper Company occupied the same position in both years with \$4,973,400 in 1906 and \$6,160,050 in 1907. In 1906 there are only three other companies, all copper companies, which produced more than \$1,000,000, whereas in 1907 there were five.

The most equitable system of taxing mines is a question upon which there is great difference of opinion. As the rate is assumed to be adjusted to the total value of the property taxed, the total value of the product in metal or mineral of mines, above a given minimum, is perhaps open to less ambiguity than a valuation of product based on net returns, as is the system applied in Montana. The Butte mines in 1907 were taxed on the following net returns:

	Net Proceeds,
Anacoda	1 1/2 \$5,456,395
Anacoda	1-B 362,790
Butte & Boston	1-B 1,239,055
Butte & Boston	1-B 10,412
Boston & Montana	1-B 7,041,988
North Butte	1-B 3,271,214
Parrot Silver	1-B 14,300
Parrot Silver	1-B 127,431
Red Metal	1-B 1,432,761
Trenton	1-B 481,624
Original Consolidated	1-B 663,260
Monidah Trust	1-B 3,053
La France	1-W 151,013
Clark-Montana Realty	1-B 188
Total net proceeds	\$20,263,482

Deductions may be drawn from the tables as to cost of production, but they will be of doubtful accuracy.

*1 1/2 means outside city limits, levy 18 1/4 mills; 1-B means inside city limits, levy 23 7/20 mills; 1-W means inside Walkerville city limits, levy 28 1/4 mills.

The Lake Superior Copper District

By C. L. C. FICHEL,*

The year 1908 in the Lake Superior copper district was noted for the vast amount of exploratory and development work done, practically all of the producing mines inaugurating this policy. The known lodes traversing the various properties were opened and great tracts of virgin ground were investigated. The producing mines throughout the district were operated consistently and production will be about the same as for 1907. Osceola will show a decided increase, Copper Range will be about the same (the increased production at the Champion and Baltic properties making up for any falling off in the Trimountain), and the Calumet & Hecla mines will, in all probability, show a slight decrease due to the conglomerate lode gradually diminishing with depth in its mineral yield, the rock now running about 30 lb. to the ton. The year was devoid of any labor troubles, or serious casualties and as a whole was very prosperous.

KEWENEAW COUNTY.

The Keweenaw Copper Company became a producer. Its Medora shaft was sunk below the 13th level and the bottom levels were extended and showed a decided improvement at depth. The Phoenix mill, owned by this company, was overhauled and equipped with Woodbury jigs and at the close of the year was handling about 120 tons of rock daily. The Keweenaw Central railroad was completed during the summer months and regular freight and passenger service was maintained between Calumet and Mandan.

The Tamarack Company operated the old Cliff property throughout the year and openings were extended on several of the fissure veins running across the property. Rock shipment averaging about 80 tons weekly were shipped to this company's mill for treatment. During the last part of the year the shaft on the Avery tract was unwatered and cleaned out preparatory to sinking.

The Ojibway company made remarkable progress during the year, sinking both its shafts below 600 ft. and exposing the lode at the first and second levels of No. 2 shaft and the first level of No. 1 shaft. This was accomplished by crosscuts, the shafts being in the footwall side; the lode opened at No. 1 shaft was especially rich. The surface equipment is complete and the railway now runs into the property.

Exploratory work was started on the Seneca tract and a shaft was sunk about

175 ft. The surface equipment was completed and is sufficient to carry the property through its development stages. The shaft is sunk in the footwall about 75 ft. behind the lode which will be reached by crosscuts. Considerable diamond drilling was done previous to shaft sinking.

The Gratiot property under the management of the Calumet & Hecla company was opened thoroughly. Both shafts were sunk deeper and drifts were extended; the showing is indicative of better results.

All five shafts of the Mohawk company were sunk deeper and drifts were extended from the various levels. At No. 5 shaft, the newest of the openings, the ground was especially good; this shaft was equipped during the year with its permanent hoisting plant. The stamp mill ran satisfactorily and treated an average of about 2000 tons of rock daily.

The Ahmeek company started sinking two new shafts to work the northern and central portions of the tract. These shafts will encounter the lode at about 1200 ft. Openings in the two producing shafts were extended and the ground opened to the south was especially good. At the fifth level of No. 2 shaft the south drift encountered a fissure of mohawkite. The company also purchased a mill site on the shores of Torch lake and began the erection of a modern four-head stamp mill which will be ready during the summer of 1909.

Both shafts of the Allouez company were sunk deeper and No. 2 shaft is approaching the lode and it is expected that it will be cut early in 1909. The lode has been opened from this shaft by a crosscut at the 6th level and a drift, connecting the two shafts, was holed through. No. 1 shaft maintained rock shipments to the mill averaging about 650 tons daily.

HOUGHTON COUNTY.

A new hoisting equipment was installed at the Wolverine's northern shaft and at the stamp mill two heads were converted into steeple compound. Conditions underground are in fine shape and the property continues one of the most successful on the lake.

The Centennial company sank both its shafts deeper and the drifts north from No. 2 shaft entered the zone of the Wolverine mineralization and excellent rock was mined. At the stamp mill, owned jointly by the Centennial and Allouez companies a 3-head addition was built to the building and two heads were installed.

The Calumet & Hecla company did a vast amount of construction work during the year; the pumping station at Lake Superior was electrically equipped and consists of a 3,000,000-gal. multi-stage centrifugal pump, with its accessories. The

station required the erection of a high-tension transmission line about 5 miles long. A series of pumps were installed underground at the north end of the property; a large addition was built to the foundry and a complete drill-sharpening plant was installed. At the stamp mill the twenty 510-h.p. boilers, comprising the new plant, went into commission and at the company's electric-power plant the third 2000-kw. generator was installed, bringing this plant up to about 11,000 h.p. The first section of the large re-grinding mill was equipped and is ready to go into regular service; throughout the mills all railway trestles were remodeled and structural steel replaced all wooden construction; this was made necessary by the additional weight of trains used on the standard-gage equipment. All the shafts on the main, or conglomerate lode were operated but the copper content of the rock gradually decreased and the available working ground in some of the shafts is becoming exhausted. The Osceola amygdaloid formation was opened extensively. All 6 shafts were sunk deeper, new ground was opened and the upper drifts were extended. Nos. 13 and 16 shafts were equipped with two skip roads and No. 15 will soon be ready. The company operated one shaft on the Kearsarge lode (No. 21) and with the additional depth and openings especially good rock was exposed. Exploratory work was carried on by this company in Ontonagon county, on the White Pines and Nonesuch tracts.

At No. 1 shaft of the Tamarack company all rock hoisting was suspended and the shaft was equipped to handle all the water from the underground openings; all water-way connections were made with the working shaft and also with the Tamarack Jr. property. At No. 2 shaft arrangements were made to install the Kimberly skip system. The company has discontinued sinking its shafts vertically, and henceforth all additional depths will be obtained by subshafts sunk on the vein.

The Osceola company materially increased its production during the year; No. 6 shaft opened up especially good ground. This shaft was equipped with 6-ton skips and its hoisting facilities were strengthened. Both the North and South Kearsarge branches of this company are in fine shape. No. 4 shaft of the North Kearsarge, the newest of the openings, disclosed the lode by crosscuts from three different levels and found it well mineralized.

The LaSalle, a subsidiary company of the Calumet & Hecla company, was opened consistently. The Tecumseh shaft showed good copper rock, but the two shafts on the Caldwell tract gave indifferent results; sinking was suspended on

*Electrical department, Calumet & Hecla Mining Company, Calumet, Mich.

this tract and crosscutting was started to open more fully the surrounding territory. Operations at the Rhode Island property were centered in drifting on the Pewabic lode from the 10th level of its shaft.

some land belonging to the St. Mary's Mineral Land company. Under such conditions development will be centered upon the Pewabic lode as the main working body.

The Arcadian changed management

shaft known as the Pontiac, or No. 9, which is down 200 ft. in good copper rock; the shaft will develop the northern portion of the tract. A new steel shaft house was erected on the site of No. 2 shaft and is a model in all respects. At

The Franklin company opened the Pewabic lode at depth by crosscuts extended from the conglomerate shaft and at the 23d level the lode was exposed highly mineralized. In all probability a consolidation will be effected between the Franklin and Rhode Island companies, including

during the year and its office was removed to Houghton, Mich. The company did not do any active work, being out of funds, but at a meeting to be held early in 1900 reorganization will be effected and work should be resumed.

The Quiney company started a new

the stamp mill the single-cylinder heads have been equipped with 24-in. single cylinders and excellent results are being obtained. This company will, if present plans materialize, take over a portion of the old Franklin workings.

The Hancock company sank its large

5-compartment shaft below the 15th level and from the 13th level started a crosscut to connect with No. 1 shaft; this shaft has reached its permanent bottom at the 14th level and all additional ground will be worked through No. 2 shaft. At No. 1 shaft the crosscuts opened the west lode and found it more uniform and of a better grade than the Hancock lode and this will be the main working lode hereafter.

The three southern shafts of the Isle Royale company, viz., Nos. 4, 5 and 6, were furnished with permanent equipment and will soon be in position to aid materially in production. This company is also developing the extension of the Baltic lode by a shaft sunk in section 11, which carries the lode.

No. 1 shaft of the Superior property was widened to accommodate two skip ways. This shaft has opened the lode by crosscuts for 10 levels; a fine grade of rock shows below the 5th level. Sinking was resumed at No. 2 shaft. The surface equipment was enlarged, additional hoisting and compressor facilities were added, and railway connections were made to the Atlantic mill, which is to treat its output temporarily. The company is on the verge of becoming a producer and has as fine prospects as any Lake Superior copper mine.

At the Atlantic mine all operations were centered at its section 16 tract, where the shaft was put down below the 18th level. The same shattered condition continued in the shaft with depth, but the extensions of the drifts, especially to the south encountered a more substantial formation. The rock was sorted the last few weeks of the year and as it accumulated was put through the mill. This shaft will be in shape, early in 1909 to maintain regular shipments.

The Champion and Baltic mines of the Copper Range Consolidated Company closed the year in fine shape; many improvements were made both at the mines and mills. The Trimountain is gradually approaching the other two in production; the ends of the property are revealing a good grade of rock and with depth a better showing is being made in the central portions of the mine. The shaft on the Globe tract, held under option by this company, cut the lode at a depth of about 1000 ft. and drifting was started but results were unsatisfactory; copper-bearing rock appeared from time to time, but it had no commercial value. This company is also diamond drilling on sections 7 and 8 to open the old Atlantic lode.

ONTONAGON COUNTY

The Elm River company started a vertical shaft on the site of an old test pit and it is down well in the ledge; when

sufficient depth has been reached it is planned to drive a crosscut east to cut the various formation supposed to traverse the tract.

The Wyandot began crosscutting from the bottom of its exploratory shaft 700 ft. from surface and encountered an amygdaloid formation carrying a small seam of copper; drifting to ascertain its condition was recently started.

The shafts of the Winona property were sunk deeper and the lode was cut at the various levels by crosscuts which revealed a satisfactory mineralization in all cases and improved with depth. The electrically operated hoisting plant went into commission and is doing regular service.

The King Philip property, under the management of the St. Mary's Mineral Land Company, was systematically opened on the Winona lode. No. 1 shaft is below the 8th level and the lode, cut at this point by a crosscut, was encouraging. No. 2 shaft is sinking close to the 2d level. A duplicate electric hoisting plant was installed at this property, and power is received from the Winona plant.

The wonderful showing, opened close to surface, at the Lake property has continued with depth. The shaft was put down to about 370 ft. without any change in the formation and drifts, extended from the 1st and 2d levels, are breasted in the same rich ground. An enlarged equipment was installed and a railway spur was laid to the shaft site.

The lands adjoining this property on the north and east aggregating about 1120 acres were taken over by the North Lake company and diamond drilling was started to open the Lake lode.

The Adventure company carried on extensive diamond-drill operations and cut an encouraging amygdaloid formation; additional drill-core data are being obtained, and when complete, shaft sinking probably will be started.

The Mass Consolidated Mining Company carried on extensive exploratory work throughout the year both by means of trenching and diamond drilling, but the nature of the results have not been announced.

The Michigan Copper Mining Company resumed the construction of its mill and "C" shaft again was put on the producing list and a much better showing was encountered on the Calico lode. This company also did a large amount of diamond drilling.

The Main lode of the Victoria property was disappointing and the company took up the search for a more consistent formation. A crosscut was started from the 22d level of its shaft and is just entering a copper-bearing formation; better results are being noted in the tunnel. Diamond drilling is being continued.

Antimony

The market for antimony in 1908 was quiet and without the sensational fluctuations in price that characterized the market in 1907. The chief factors which influenced low prices were heavy shipments of Chinese ore which readily cared for the demand and the restricted use of the metal by the railroads due to the financial depression. Throughout 1908 prices for Cookson's fluctuated between narrow limits; in January the average price was 9.344c. per lb. and in December it was 8.20c. per lb.

Hallett's brand was very scarce at the close of the year and Hungarian antimony was not prominent. Low prices affected these brands more than Cookson's.

But little antimony ore was mined in the United States in 1908 and the only smeltery in operation was that of Mathison & Co., at Chelsea, Staten Island. Low prices prevented the great majority of mines from extensive production and many were not operated at all during the year.

AVERAGE PRICES OF ANTIMONY.

During the first half of 1908 France, according to *Min. Journ.*, Oct. 5, 1908, produced 38,626 tons of acid bessemer ingots, 807,192 tons of basic bessemer ingots, 508,386 tons of open-hearth steel ingots, and 10,793 tons of crucible and electric steel. The total steel production was 1,364,979 tons, as compared with 1,318,530 tons in the corresponding half of 1907. The production of coal during the first half of 1908 comprised 18,116,143 tons of coal and 383,499 tons of lignite.

The output of copper ore in the United Kingdom in 1907 was 6792 long tons, against 7758 tons in 1906. In 1893 the production of ore and precipitate was about 210,000 tons, valued at more than £1,000,000.

The Production of Lead and Spelter in 1908

Statistics of Production and Price—Imports and Exports—A Review of Mining Conditions—The Markets—Production of Zinc Oxide

LEAD, 323,841; SPELTER, 207,735 TONS

The bulk of the domestic lead production comes from two districts, viz., southeast Missouri and the Cœur d'Alene, of Idaho. If we include Joplin, Mo., Park City, Utah, and Leadville, Colo., we account for nearly 80 per cent. of the production of the United States. The Missouri lead ore is non-argentiferous. Almost all the other lead ore is argentiferous and is treated by the silver-lead smelters. With them the lead is not only an object of recovery for its own sake, but also it plays the part of collector for the precious metals of ores containing no lead that are smelted along with the lead ore. This condition is of great economic importance in determining the price for lead. The cost of producing lead in southeast Missouri is now about 3c. per lb., delivered at St. Louis. In the Cœur d'Alene it is 2.5

great life to this market. The average price for the year was 4.24c., which may be compared with 4.53c. as the average for the 10 years 1898-1907; this is a fair showing for 1908. However, lead is not a good criterion of commercial conditions in general. About 35 per cent. of the domestic consumption is for making white lead and oxides, the business in which was good in 1908. Labor being plentiful at reduced wages, many persons took advantage of this favorable opportunity to do necessary painting.

Mining continued in southeastern Missouri without any check to speak of throughout 1908. There was but little recession in the output of the Joplin district. Combining the production of these two districts, Missouri again holds the premier place among the lead-mining

mines of the Cœur d'Alene were adversely affected by the declining price for silver, the cost of producing their lead being affected greatly by the amount realized for that by-product. Apex litigation was inaugurated in 1908 between the Federal Mining and Smelting Company, and the Bunker Hill & Sullivan company, and the Cœur d'Alene is now to be afflicted with that curse. Undoubtedly the expense of this litigation will materially increase the cost of production to both companies.

Elsewhere in the United States there were no important developments in lead mining in 1908. In general the Western smelters curtailed operations during the early part of the year, resuming later on. Among the refineries, that of the United States Smelting, Refining and Mining Company, at Grasselli, Ind., was the only

COURSE OF LEAD PRICES DURING 1908. PLOTTED FROM THE MONTHLY AVERAGES

to 3.5c., delivered at New York, when the silver by-product realizes 50c. per oz. These mines alone cannot supply domestic consumption under normal conditions. A considerably higher price is necessary to maintain the production of Park City, Leadville, and a hundred miscellaneous mines; and unless the smelters have their ore they cannot treat so much gold and silver ore as is offered. Consequently the price for lead affects not only the lead mines but also many mines that yield precious metals only.

The year 1908 began with a large stock of unsold lead on hand and the price 3.55c., New York, which was only a trifle above the lowest of the panic period. During 1908 there were constant fluctuations with a generally upward trend until August, after which the market fell off a little, closing at about 4.20c. The stock on hand appears to have been reduced to ordinary and comfortable proportions, but at no time during the year was there any

States. There is not yet in sight any limit to the productive capacity of the mines of southeast Missouri, except the ability to secure the necessary labor. The ore deposits are of immense extent, and great improvements in the methods of mining, milling and smelting have been, and are still being made.

Some of the mining companies of the Cœur d'Alene affected to be seriously hurt by the low price for lead at the beginning of the year, and curtailed their production. In some cases this action was doubtless justified, certain of the mines having been worked to such depths as to be no longer profitable. Indeed, the Tiger-Poorman mine, at Burke, of the Federal Mining and Smelting Company has been abandoned. On the other hand, certain companies, especially the Bunker Hill & Sullivan, can operate profitably at a lower price than was reached in 1908. This great company produced on a large scale throughout the year. All of the

one to be closed entirely. This was made necessary by the suspension of operations at the works of the United States Smelting Company, near Salt Lake City, because of the smoke injunction. That company developed a process for neutralizing the acid in the smoke, after which smelting was resumed.

The mines at Eureka, Nev., were idle during 1908. The old mines at Pioche, Nev., are being reopened, and there is talk about these becoming an important source of lead production.

Production of Lead

The production of refined lead in the United States in 1908 is given in the accompanying table, the statistics of which are based on reports from all of the refiners stating their actual production for the first 11 months and their own estimates for December. Inasmuch as these

reports were for the most part made after the middle of December, the estimates are probably close, but in these preliminary statistics there is usually some uncertainty as to the separation of desilverized lead of domestic and foreign origin.

PRODUCTION OF REFINED LEAD. (IN TONS OF 2000 LB.)

Class.	1907.	1908.
1. Desilverized	213,383	182,401
2. Antimonial	9,613	12,491
3. Southeast Missouri	108,510	110,059
4. Southwest Missouri	17,533	17,590
5. Miscellaneous	790	1,000
Total domestic	350,130	323,541
Total foreign	76,016	80,293
Grand total.	426,146	404,134

(1) Does not include the lead, chiefly of Missouri origin, which is desilverized by one smelter in Illinois and is here entered under Class 3. (2) The production of antimonial lead which used to be divided according to domestic and foreign, in 1907 and 1908, has been wholly entered under domestic. (3) Includes two smelters in Illinois, which use chiefly ore from southeastern Missouri. (4) Includes one smelter in Kansas, which uses ore chiefly from southwestern Missouri. (5) Includes small smelters in Wisconsin, Illinois and Iowa.

IMPORTS AND EXPORTS OF LEAD.

(FOR FIRST 11 MONTHS OF THE YEAR.)

(IN TONS OF 2000 LB.)

	1907.	1908.
Imports:		
In ore and base bullion	62,973	97,092
Pigs, bars and old	9,164	2,753
Exports:		
In ore and base bullion	47,467	67,924

The Lead Market at New York in 1908

An upward movement, culminating in August, and a subsequent downward movement, which appears not to have exhausted itself at the close of the year, characterizes what has been an unusually erratic market. Under the impetus of an improvement in the general situation, heavy buying on the part of speculators took place in the first months of the year, reinforced by purchases on the part of consumers in anticipation of a better business. While the output in Missouri assumed normal proportions as early as January, production in the West continued heavily curtailed until the spring months, and this fact helped greatly in the distribution of the large stocks which had accumulated and the advance in the price which was almost uninterrupted until August.

The business of manufacturers was more or less of a dragging nature throughout the entire year, with the exception of the white-lead branch, where up to November the requirements were of very large volume. An equilibrium was reached in the middle of the year. At that time the resumption of Western mining operations on a normal scale made itself felt in the available quantity of marketable lead, but when the white-lead manufacturers ceased their purchases on a heavy scale, upon entering their dull

season at the beginning of fall, the rate of offerings again overtook the requirements, and a rapid decline ensued. Prices at the close of the year again reached a level where they may be called cheap from a general point of view.

It is not unreasonable to assume that prices are now not very far from bottom, the expectation being general that those branches of the lead business which have been hitherto neglected, particularly lead-covered cables, sheets, pipes and miscellaneous products, will be greatly benefited by the increase in corporate activity and in the building trades, which for these particular purposes came too late to be felt in the fall, and now must wait until the winter has passed.

At the beginning of 1908 the market stood at 3.55@3.60c., New York, and a gradual and slow advance established prices at 3.70@3.75c. at the close of the month. This level was maintained well into March. The surplus which was left over from the previous year had been largely distributed by that time, and the market was depending upon the actual lead output which was restricted by the reduced activity in Western mining centers. A realization of this brought consumers and speculators into the market, and in consequence a sharp advance took place to 3.90@4.4c., New York. There was not much change from these figures until late in April. The spring season is always the busiest for the lead manufacturers, and the resulting influx of increased business brought them into the market for correspondingly larger quantities. Under the influence of this, prices reached 4.05@4.10c. toward the end of April.

The better outlook encouraged resumption of mining operations in the West on a normal scale, but the heavier production did not reach the market until several months later, and meanwhile the shortage of supplies facilitated the forward movement, a steady appreciation taking place throughout May and June, when sales on a large scale were effected at 4.47½@4.52½c., New York. The most urgent demand being satisfied, the market reacted in July to 4.40@4.45c., New York. There was a rally from this level during August, due to speculative influences, which caused an advance to 4.57½@4.62½c., New York, the highest point reached during 1908. This movement was short-lived. The weight of offerings became heavier during September, owing to the increased supplies turned out by the Western mines, which by that time had passed through the refining works.

The last three months of the year recorded, with one short interruption in November, a retrograde movement, which

is still a factor at the end of the year, the close being steady at 4.15@4.20, New York.

New York, cents per pound. London, pounds sterling per long ton.

White Lead in 1908

There was an active demand for white lead during the early months of 1908, due in part to the necessities of paint grinders and other large consumers and distributors, who had allowed their stocks to run down under the depression of the latter part of the preceding year, to a point that gave them no surplus from which to meet the anticipated requirements of the spring business. The consumption of paints during the first half of the year was not all that had been hoped for; there was no general revival of the building industry, and the last quarter was distinctly disappointing because business was not greater than in the corresponding months of 1907, when the depression was at its worst. In spite of these facts, however, sales of white lead showed an increase over 1907, and this seems to have been an exceptional feature of the paint industry. The reason for this is chiefly the proportionately large demand for pure white lead or high-grade paints due to the educational work of the paint laws enacted in several States and the wide discussion that has attended their adoption.

LEAD CARBONATE

In spite of advancing prices for pig lead, consumers of the carbonate were given the benefit of the low-cost metal bought by corrodors during the latter part of 1907, and there was no change in quotations from the list established in December, 1907, until the latter part of June, when an advance of ¼c. was made. This advance was maintained on lead in oil until Dec. 10, 1908, when there was a reduction of ¼c. and the year closed at 6½@6¾c., the prices ruling a year ago. This is the base price for lead in kegs of 100 lb. and upward, with an advance of ¼c. on 25- and 50-lb. kegs, and ½c. on 12½-lb. kegs. This differential is necessitated by the custom, adopted by all corrodors during the year, of making all pack-

ages full net weight instead of including the weight of the wood in the invoiced weight as was the previous custom on sizes under 100 lb. Where the cost of the package bears so large a proportionate relation to the value of the contents it has to be charged for in some form, and as the newly enacted paint laws generally require that packages shall be branded at actual net weights, the added price is necessary. It is generally expected that in the near future a further innovation in the trade in paint in oil, will be the adoption of steel packages in place of wood, for all sizes from 100 lb. down. The high cost of cooerage makes this a change in the direction of economy for the corrodor, and from the standpoint of the consumer the metal package has many advantages.

The last reduction in price applied to lead in oil only and was due chiefly to the wide margin that had existed all during the year, and especially during the fall months, between the price of dry lead and that of lead in oil. This margin has been sufficient to give paint grinders an exceptionally good profit, even though their dry lead has averaged them a little above last year.

As a matter of fact quotations on dry lead were largely nominal throughout the year, and the bulk of the sales were even below the nominally quoted price for car-load lots. During the first half of 1908 the price generally quoted was 5½¢, and this was fairly well adhered to as a price to grinders, although sales at 5¼¢. were by no means exceptional. The same nominal quotation prevailed during the last six months, but there were more sales at 5½¢. than at the higher fraction, and the largest corroding interests entered into heavy contracts with grinders, and other large consumers during October at 5¼¢. Since then, however, the business has been mainly at 5½¢.

LEAD OXIDES

Lead oxides did not have as satisfactory a year as did the carbonate. While there was some improvement in demand as the year progressed, many of the large consumers of red lead were practically out of the market due to a lack of structural work, and in some other industries litharge was substituted for red lead because of an unusually wide difference in cost. Prices for both oxides, and especially litharge, were unsatisfactory to manufacturers, since some of the makers, who have recently become active in the market, have freely offered their product at narrower margins above the cost of metallic lead than had almost ever before prevailed. As a result published quotations were wholly nominal, and the bulk of the business in red lead was at 6¼ @ 6½¢.; these figures, of course, represent the prices to large consumers, and in casks. Through the ordinary channels of distribution prices

have ranged from 6¼ @ 7¼¢. as to quantity and size of package, for both oxides.

The year closed with an evident expectation of a good spring business in all forms of high-class paints, but with marked conservatism on the part of large buyers as to present purchases based upon a lack of confidence in prices. The buyers of all lead products now watch closely the published quotations for pig lead and base their ideas of the value of the carbonate and oxides thereon; and while manufacturers do not always meet these ideas, they have a tendency, on a declining metal market, to keep the demand from this class of buyers down to their current running requirements.

Southeast Missouri Lead District

By H. A. WHEELER*

The output of the southeastern lead belt of Missouri closely approximated 104,000 tons in 1908, with an estimated value of \$8,320,000. This is high-water mark as regards tonnage, for it exceeds the highest previous production, that of 1907, by about 6 per cent., but on account of the much lower metal prices, especially in the early part of the year, the production of 1908 is nearly 25 per cent. less in value.

In view of the discouraging condition of the market at the beginning of the year, this record is very satisfactory, and emphasizes the healthy, basic conditions prevailing in the district. It continues the record of continuous growth—a record that any old mining district might well envy—and while hitherto the output has increased at the rate of 10 per cent. or more annually, it should be borne in mind that the above growth of 6 per cent. is figured on the highest previous production.

The severe panic in the latter part of 1907 caused considerable curtailment in the output last winter, but it also enabled the rapidly rising wages to be lowered to a more reasonable basis. When the lead market unexpectedly showed such healthy improvement last spring, the larger producers resumed full-time work and continued to work full time up to the close of the year.

The increase in the output resulted from improvements largely made in 1907, as in 1908 no new work was attempted until the latter part of the year. No new ore-bodies were discovered; nor were any new companies floated in 1908. As the market maintained its improved condition, toward the end of 1908 it encouraged the starting of betterments that should increase production considerably in 1909, if the present bright outlook continues.

The output, as usual, was almost entirely derived from the five large producers in the Bonne Terre and Flat River

camps in St. Francois county, especially as the depressed market was felt much more severely by the smaller producers in Madison, Washington, Jefferson and Franklin counties. But the decreased tonnage in these camps was not enough to affect materially the results of the district. The output of Madison county, which includes the Mine la Motte and Fredericktown camps, amounted only to about 4 per cent. of the total, while the production from the old shallow diggings of Washington, Jefferson and Franklin counties was less than 1 per cent. The unusually small output of the latter is not due to exhaustion, but rather to the sensitiveness of the mines in that area to a low market and to their slowness in recovering from the benumbing action of the severe panic of 1907. For, although the market rallied from an opening price of 3.4 @ 3.5¢. at St. Louis to 4.25 @ 4.3¢. later in the year, this failed to restore confidence among the small leasers who operate in the shallow diggings.

The searching for new orebodies with the diamond drill that was so conspicuous in 1906 and 1907 and which was so abruptly brought to a close by the panic has been taken up again on a large scale by only one of the large companies. Some diamond drilling was done by the other companies in 1908, but on a relatively small scale and mainly to define and extend the orebodies now being worked. The steady absorption by the large companies of mineral-bearing lands in the lead belt that had been in progress until the panic has not yet been renewed; but the few good tracts remaining are likely to soon be taken over as the times improve, for, with the steadily growing outputs and increased size of the mills, the present orebodies are being rapidly exhausted and foresight requires the accumulation of virgin properties to supply future ore reserves, especially while the prices are still so moderate. Prices that today look high at \$100 to \$300 per acre are compared with prices of \$50 to \$100 an acre that ruled scarcely 10 years ago will probably look extremely cheap 10 years from now.

An important innovation was introduced in this district in 1908 by the starting of an electric power plant in which gas engines supplied by producers are the prime-movers. Although the district, being only about 60 miles from the Illinois coalfields, enjoys probably the cheapest coal of any metal-mining district in the country, two 2400-h.p. plants were erected to still further reduce the fuel costs by utilizing the much greater economy of gas engines; these were installed to replace compound Corliss steam engines, equipped with condensers. But, since nearby bituminous coals can be laid down at the metal mines for \$1.75 to \$2.50 per ton, the margin for economy is not as attractive as usual. This will be especially so if higher grade coals have to be shipped in to obtain

*Mining engineer, 510 Pine street, St. Louis, Mo.

efficient work from the producers. Local experience in operating gas producers with western Illinois coals has shown that, as these coals are so high in sulphur and ash, in the past it has been more profitable to use the higher-grade and more expensive coal from Indiana or southern Illinois.

THE ST. JOSEPH LEAD COMPANY

This pioneer company in the operation of the modern disseminated mines still holds its well earned prestige of being the largest, most important and most profitable of the Missouri producers, in spite of being the oldest. It is still producing heavily from its No. 1 mine, which is now more than 40 years old, and its latest shaft, the No. 13, was recently sunk to open up an extension of its famous Bonne Terre orebody. While this company reduced its output 50 per cent. and entirely stopped extensive improvements in the latter part of 1907, the mines were reopened on full time early in 1908, and later in the year much of the new work was resumed. Betterments at its model town of Bonne Terre have been continued by adding to the new sewage system, and by the building of a large, attractive new store, now nearing completion. The second story of this building will be devoted to the use of the local Mine Club.

In October the gas-engine power plant of this company, at Bonne Terre, was completed and is now in successful operation. It consists of three 600-k.w. Westinghouse generators each directly driven by duplex, horizontal gas engines of the Snow type. The power plant is housed in a well lighted, fireproof, steel building that is equipped with a 10-ton traveling electric crane. At present the alternating current is distributed at 6600 volts to the nearby mines and mill, but later it is expected to enlarge the plant and send power to the more distant mines. The gas is furnished by two batteries of duplex producers of the Loomis-Pettibone down-draft type, which are housed in an adjoining steel building, with an intermediate large gas-holder.

The St. Joseph company is operating eight shafts. These supply the old or No. 1 mill at Bonne Terre, having a capacity of 1,500 tons, and the new or No. 2 mill at Owl Creek, having a capacity of 1200 tons. The concentrates are shipped 30 miles north to the company's smelter at Herculaneum, on the Mississippi river.

THE DOE RUN LEAD COMPANY

The Doe Run Lead Company has completed the installation of a gas-engine power plant at its No. 1 shaft at Flat River—a duplicate of the St. Joseph company's plant—and has resumed the construction of the concentrator at West Elvins, on which work was stopped by the panic. This mill will have a capacity of about 1500 tons and is expected to be in operation by July 1, 1909.

Like the St. Joseph company, the pro-

duction was cut down 50 per cent. in the latter part of 1907, but work at full capacity was resumed in the early part of 1908. Four shafts are being operated, from which the ore is shipped ten miles south to the 1500-ton mill at Doe Run; the concentrates are then shipped to the St. Joseph company's smelter at Herculaneum.

THE FEDERAL LEAD COMPANY

The Federal Lead Company has entirely recovered from the partial shutdown in the latter part of 1907, and is today making the largest production in its history. Its new No. 2 mill at Central is being re-modeled by taking out the 3-compartment Hartz jigs and replacing them with Hancock jigs. This is resulting in a marked saving in labor, power and water, besides materially increasing the capacity. When other improvements are completed it is expected that the No. 2 mill will have a capacity of 3500 to 4000 tons per day, making it by far the largest mill in the district as well as in the Mississippi valley. The company is operating its No. 1 mill, which has a capacity of about 1000 tons per day.

A new shaft, the No. 11, is being sunk on the south side of the No. 2 mill to tap the old Central orebody, and work is shortly to be started on Nos. 9 and 10 shafts; the sinking of both these was discontinued in the latter part of 1907. Six shafts are being operated at present, but before the close of 1909, nine will probably be supplying ore.

THE NATIONAL LEAD COMPANY

The National Lead Company kept steadily at work and made an excellent record for a busy, active year that has been far from unprofitable. Equipped as it is with one of the best and most compact plants in the district, it was probably the best money-maker during 1908, for it never curtailed its output, and its up-to-date plant was under no expense for improvements. Four shafts supply the 1500-ton mill; these are only $\frac{1}{4}$ to $1\frac{1}{2}$ miles distant from the mill.

The Desloge Lead Company maintained its usual output and did not attempt materially to curtail its production during the depression. The new No. 5 shaft has been completed; this shaft is not situated conveniently to the mill, being about four miles distant, but it promises to prove a valuable producer. The new orebody opened up by this shaft lies almost over the line in Washington county. The company's small plant of Flintshire or air furnaces has been operated on the Desloge brand of pig lead, but, as this plant is too small to smelt all the output, most of the concentrates have been shipped to the Illinois smelters. The company's 1000-ton mill is supplied from three shafts that are $\frac{1}{2}$ to 4 miles distant from it.

The plant of the Mine La Motte company in Madison county has been equip-

ped with a new 500-ton mill under the present Pittsburg management. The output was not pushed in 1908 owing to the low market, but instead the reserves were increased and the property developed. The lease of the old copper-mine tract that was sub-let by the Mine La Motte company to the Hudson Valley Mining Company has been transferred to the Eastern Lead Company which operated most of the year on a royalty basis.

The North American Lead Company at Fredericktown, in Madison county, continues to be operated as a copper property and the small amount of lead that it recovers in working the copper sulphides is merely a by-product that is shipped away to be smelted.

The Madison Lead and Land Company, which operates the old Catherine mine in Madison county, partially restricted its output during 1908 and ran only one of its two mills.

Spelter

The bulk of the production in the United States continues to be derived from the Joplin district. The fact that the resources of that district have been seriously diminished is of determining influence in the spelter industry. If it had not been for the appearance of the Rocky Mountain zinc ore, the rejuvenation of mining in Wisconsin, and the importation of Mexican ore during the last five years, there would undoubtedly have been a spelter famine. In spite of the new supplies it has been necessary to mine a very large quantity of ore at Joplin that yields only $2\frac{1}{2}$ to 3 per cent. of concentrated mineral, which could be done only at an advance in price for the ore and consequently for spelter also. This condition is becoming more and more emphasized.

There is not now in sight any supply of cheap ore that might oust the Joplin district from its present position of premier zinc producing district. Consequently continuance of a high level of price for spelter must be expected, because it will be necessary to enable the Joplin sheet ground mines to continue to operate. The price might rise inordinately high under the demand for increasing consumption, but it will be restrained by supplies of ore from other districts. However, the other districts, except perhaps Wisconsin, will be unable to furnish cheap ore; because in spite of their advantage in a higher grade of crude ore, their cost of mining and milling per ton of crude ore is high (in most cases inevitably high), and their concentrated product is subject to high freight charges, owing to remoteness from the smelting centers. The experience of 1907-08 has shown that a price of less than 5c. for spelter tends to check production from these mines.

Yet it would be unjustified to say that

this condition will continue indefinitely, inasmuch as new zinc-producing districts may be discovered. None that can be pronounced as promising a substitute for Joplin is now in sight, but geologists consider that similar deposits may reasonably be expected along the skirts of the Ozark uplift, and the development of important mines at Miami, Okla., in 1908, lends color to this belief. Dr. Keyes, formerly State geologist of Missouri, has recently expressed the opinion that the name of "Joplin district" has become a fetish, upon which attention has been concentrated to the exclusion of other prospects that may develop into important zinc-producing centers. If this be so, and Dr. Keyes is not alone in the opinion, it is to be expected of course that sooner or later further zinc resources will be discovered in Missouri, Kansas and Oklahoma.

The spelter market was very unsatisfactory in 1908. It began with a greatly decreased production, a stock of 33,000 tons on hand, and the price $4\frac{3}{4}$ ¢, New York. Spelter is a good criterion of domestic business, inasmuch as practically the whole production is consumed in this country, while 80 per cent. of it is used by the galvanizers and the brass makers, wherefore spelter connects with both the steel and the copper manufacturing industries. During the first half of 1908 the demand for spelter was slack, but the smelters laid off so many furnaces that the small demand led to an advance in the price; however, by mid-year the latter was only $\frac{1}{2}$ ¢, above that of the beginning and the unsold stock had increased, estimates varying from 35,000 to 50,000 tons. The gradual improvement in the demand for consumption induced the smelters to fire more furnaces in the second half of the year, and the price averaged materially better, being a little over 5¢. in November and December, but 1908 closed with a large unsold stock in the hands of the smelters, including what they were holding for speculators, the account of the latter being rather large. Applying to spelter the remarks that we have made respecting copper, the stock on hand at the end of 1908 does not loom large, being less than two months' consumption, but in this industry it is not common to have an unsold stock in first hands of more than 2 or 3 per cent. of the annual production.

The statistics given in a following table show a large decrease in the spelter production and also in the consumption as compared with 1907. The Joplin district does not show a corresponding decrease. Its production of ore in 1907 was 286,500 tons; for 1908 its output was about 256,000 tons. These figures correspond with about 143,000 and 128,000 tons of spelter respectively. Wisconsin made a small increase in 1908. It appears, therefore, that the Rocky mountain districts and the ex-

porters of ore from Mexico suffered most. The year was one of the most disastrous on record for the smelters, whose competitive bidding for the necessary Joplin ore wiped out all margin for profit, of course to the advantage of the miners. This was a powerful factor in sustaining the Joplin production. Another factor was that many miners discharged by companies unable to work at a profit went to the old diggings and earned their living by old-fashioned hand work, thereby contributing to the increased total.

In spite of this mulcting of the smelters, the operators in the Joplin district found it hard to realize any profit and there was great complaint about the adverse conditions. The fact is, of course, that the old lens deposits, yielding 5 per cent. ore, have been to a large extent exhausted, during the last five years and a large part of the production has had to be derived from the "sheet ground," which yields only $2\frac{1}{2}$ to 3 per cent. Prices for the concentrated product rose correspondingly and the producers were able to do finely up to the latter part of 1907. Yet, even under the adverse conditions of 1908, the Joplin district was immensely profitable, although not to the operators. The latter work generally upon leased land and pay the fee-owner a royalty upon what they produce. This royalty may have been reasonable when richer ore was mined, but under present conditions it is outrageous. Consequently the mining profit is going to the fee-owners. The operators command pity in their present situation, but they have made no serious or concerted attempt to secure a readjustment of the royalty question.

The works of Hegeler Bros. at Danville, Ill., were put in operation in 1908, but they had been completed in 1907. Otherwise there were no new constructions in 1908. Indeed, at least one plant begun in 1907 was abandoned. Few, if any, of the older smelters made additions to plant. Several small works remained idle throughout the year. Others were idle for longer or shorter periods. No one operated at full capacity.

There was a large increase in the zinc production of Australia in 1908, and the treatment of the mixed sulphide ores of Broken Hill now seems to have been successfully solved. The Zinc Corporation which experienced a great deal of difficulty during its experimental period finally succeeded in overcoming difficulties and during 1908 established itself upon a profitable basis. From now onward this company will probably make a large production. The Broken Hill zinc ore has become a highly important factor in the European market, where it has displaced a good deal of the ore formerly mined in Spain and other European countries. Although the Australian ore is not of the most desirable character for smelting,

nevertheless it is advantageous to smelters to be able to contract for a long period for a large supply of ore of even character. Certain of the Broken Hill companies have sold their output for eight years ahead.

Toward the end of 1908 the convention among European zinc producers, under consideration all through the year, was consummated, but previous to the appearance of this article it has not been publicly announced. This convention appears to be the most severe and most scientific of any that has been organized in the zinc industry of Europe. Its fundamental idea is restriction of production to conform to the requirements for consumption at a certain price for spelter, which appears to be £20/23. If the unsold stock of spelter, to be reported monthly, exceeds a certain amount, there is to be a restriction of production according to schedule based on the excess of stock. Or if the price for spelter falls below £20 there is also to be a restriction of production. The regulation of production is to be in the hands of three commissioners. Bad faith on the part of any member of the convention, or failure to comply with the allotment, is to be punished by a fine. The members of the convention deposit with the commissions good securities as a guarantee for the collection of the fine. All of the zinc smelters of Europe, with two or three insignificant exceptions, have joined this convention. The convention has fortified itself against the entrance of new interests in the smelting business by associating with itself some of the largest banking interests of the Continent, including the Deutsche Bank, which on its part undertakes to refuse to assist in the financing new enterprises.

Production of Spelter

According to the accompanying table the production of spelter in the United States in 1908 decreased by about 33,000 tons. The statistics for 1908 are based on reports from all of the producers, who have given their actual production for the first 11 months of the year, together with their estimates for December. Inasmuch as the bulk of the reports were made subsequent to the middle of December, it is probable that the estimates for that month are very close.

A large number of the producers reported their unsold stock, as of Dec. 15, 1908, these reports including the amount held in storage for other parties. It appears from these statements that smelters who produced 147,870 tons of spelter had 20,112 tons in stock at their works. Estimating the stock of other smelters as being in the same proportion, the total stock of spelter in first hands in the United States, Dec. 15, 1908, was approximately 28,000 tons. On this basis, the de-

livery into consumption is computed in the second table.

The Spelter Market in 1908

The large accumulations carried over from 1907 exerted an influence which was felt throughout 1908. At the opening of 1908, weak holders had been fairly well eliminated and the existing stocks were in a large measure concentrated in strong hands. Production was at low ebb. The consuming community began to emerge from the demoralization incident and subsequent to the panic. The purchases of spelter for legitimate requirements had been practically nil for some months. The tendency everywhere was to work up the stocks on hand to the lowest point possible, which policy was facilitated by minimum requirements.

Meanwhile the production has adjusted itself to this state of affairs. Unlike other base metals, the greater percentage of zinc ore is obtained from small properties, the operation of which can be, stopped without serious sacrifice. The cost of idleness leaves a very small margin for losses incurred through sales of ore below cost, so that whenever spelter prices show a permanent decline, the production is automatically checked, depending upon the cost of producing in various mines. The proportion of the output which can be produced below 5c., St. Louis, as compared with the total requirements, is growing smaller in proportion to the growth of the total requirements, and this was clearly illustrated in the market developments during 1907 and 1908.

At the opening of 1908, the reduced output was just about sufficient to supply current requirements. When it was found that stocks were not increasing, speculative buying became an influence in the market and brought about an appreciation in the price, from 4.15c., St. Louis in early January, to 4.40@4.45, St. Louis at the end of that month. The movement made further progress in Feb-

ruary, during which month there was an uninterrupted advance to 4.65@4.70c., St. Louis. Realization of speculative holdings caused a decline in March to about 4.50c., St. Louis, and around this level the market fluctuated within narrow limits until well into May.

During all these months the demand was never large enough to enable liquidation of the old stock. In consequence, some of the first-hand holders lost patience and in their efforts to force sales, depressed prices throughout June and July, bringing about a decline to 4.27½@4.30, St. Louis. They, however, accomplished their purpose by shifting a good portion of the stock to consumers, who wisely took advantage of this opportunity to replenish their empty yards at low prices.

The revival in general business during the fall months was reflected in the spelter market through increased business not only from galvanizers, but also from the brass manufacturers, who then, for the first time in over a year and a half, became buyers of anything like normal quantities. As a result, an advance started in August, which continued slowly but steadily throughout the remaining months of the year. The rise would doubtless have been more rapid if it were not that the remaining surplus is being gradually fed out with the current output. This, in itself, illustrates that the output is not adequate to meet current requirements, even though requirements of consumers have not yet attained normal proportions. A further increase in the consumption can only be satisfied at higher prices, without which a corresponding enlargement in the output of ore is not to be expected. The market closes firm at 4.97½@5c., St. Louis.

New York and St. Louis, cents per pound.
London in pounds sterling per long ton.

In Western Australia there are 29 State stamp mills and 21 State cyanide plants. Prior to Jan. 1, 1908, 505,286 tons of gold ore was treated, and gold amounting to £203,6156 was extracted in the stamp mills and £277,166 in the cyanide plants, while tin, valued at £52,915 was obtained from the 31,166 tons of tin ore treated in State batteries.

Zinc Oxide

The production of zinc oxide and zinc-lead pigment in 1908 was 65,100 tons, valued at \$5,876,040, against 85,300 tons, valued at \$7,731,100 in 1907.

Zinc and Lead in the Joplin District

By JESSE A. ZOOK*

At the beginning of 1908 conditions in the Joplin district were bad owing to the financial panic. This condition continued until toward the end of September. However, as soon as the mine owners and miners adjusted the wage scale an increasing production followed, and, although the margin of profit for the mines in the sheet-ore area was comparatively small, yet prices for zinc and lead concentrates were high enough for the richer properties to resume production. Shipments increased from 14,000 tons in January to 20,000 tons in February. The average per month continued at approximately this figure until October, when the output increased to 25,000 tons for the month.

The more rapid recovery of lead prices, from the extremely low point at the close of 1907, made it possible to resume mining operations at many lead-zinc mines, especially in the sheet-ore area, that could not have been operated but for the sharp demand for and strong prices of lead. Instead of representing the profit of the mine as had been frequently the case previous to the panic, lead had to bear a portion of the expense of operating the mine. Development opened up new orebodies in outlying camps and in the areas where the ore is easy to concentrate; these deposits helped to maintain the average production.

DEVELOPMENTS IN 1908

Much development work was done during 1908 along Springs river northwest from Carthage to Alba, and northeast from Alba. The richer of these newly found orebodies added materially to the output of this part of the district, for many of the older mines of Alha-Neck have been abandoned. New discoveries in the Spring City-Spurgeon mines in Newton county south of Joplin kept pace with the abandonment of worked-out mines. This area, aside from the channel deposits, produces principally silicate of zinc. The panic halted underground development around Sarcocite and Reeds, southeast from Carthage, but a large amount of prospecting was done with drills.

South and southeast from Galena con-

*Statistician, Joplin, Missouri.

siderable drill prospecting was done in 1908, and some ore was found. Low ore prices had little effect on curtailing the work of drill prospecting, but it retarded development work all over the district. A few lens deposits were developed west and southwest of Joplin, but no effort was made to develop the disseminated deposits west of town, as that ore requires higher prices than those prevailing in 1908 to be profitably mined.

other parts of Oklahoma may become producing mines before the close of 1909.

THE INCREASED PRODUCTION IN OKLAHOMA

The phenomenal increase of Oklahoma came almost wholly from the new camp of Miami where a wonderfully rich deposit of zinc and lead was discovered in 1907. This deposit lies in horizontal layers or sheets in a blanket form; the thick

output, a number of new mills are just preparing to produce, so it is believed that in 1909 the Miami camp will double or treble the tonnage produced in 1908. Miami is burdened with excessive royalty, the rate being universally 30 per cent. The land was leased in large tracts by the parties who discovered the ore while drilling for water, and they placed the royalty base at the maximum assessed in the older camps of the district. Toward the end of 1908 drill prospecting indicated the occurrence of ore in other parts of Ottawa county; at least three of these new areas look promising.

AUTOMATIC SHOVELS UNDERGROUND AT JOPLIN

Automatic shovels may be used extensively in the mines of the Joplin district during 1909. The American Zinc, Lead and Smelting Company took the initiative, installing one during 1908; another is ordered for early delivery in 1909. The use of these shovels is partly an experiment in the Joplin mines, and the shovels will need adaptation to the local conditions to be wholly successful. Upon the absolute necessity of some means of increasing the output of ore depends future profits of zinc-lead mining in this district. It is from no disposition to force a lower wage scale that power shovels are to be installed, it is simply a question of obtaining a larger output. The supply of American-born shovelers is about all utilized. Some operators favor hiring Italian laborers for this work, but the automatic shovel is now receiving first attention. If the shovel can be made to do the work, even at a slightly increased price per ton, and will increase the output sufficiently, its use will prove profitable. This problem of handling the ore underground will probably be solved in 1909.

A NEW BASE-PRICE FOR ZINC ORES

The enlarged production of zinc ore from Miami, carrying an average of 5 per cent. of iron, was the foundation of a new system of basing ore values. As prices advanced toward the close of 1908, and all grades of ore grew in demand, one of the smeltermen discovered that he could afford to buy this ore with no deduction for iron, and a price based on ore containing 30 per cent. zinc was made, with \$1 per ton advance for each 1 per cent. of zinc above 40 per cent., and with no deduction for the iron in the ore. As high as \$22.50 per ton was paid for ore containing 40 per cent. zinc. This was equivalent to \$42.50 per ton on the 60-per cent. zinc basis, and as this ore carried 6 per cent. of iron without penalty it equalled a base-price of \$48.50 per ton, while the best ore in the district was selling at \$42.50 to \$43 on a 60-per cent. basis.

This change in base-price opened the

AN INCREASED PRODUCTION

Aside from a general resumption of operations in the sheet-ore area that may be looked for with higher metal prices, new production will come from the points where prospecting and development work during the last two years have indicated favorable ore deposits, as mentioned under the heading of developments in 1908. The Quapaw area, southwest of Baxter Springs, should show an increased output, as "wildcatting" has stopped and legitimate development work is being pushed. Miami will increase its output, and some of the recent drill discoveries in

sheets of rich ore are found throughout an area $1\frac{1}{2} \times 3$ miles, while thinner sheets of ore extend outward from the central body. The ore is coated with oil and asphaltum; without vanning from 3 to 7 per cent. of iron pass into the concentrates. On account of the presence of oil, concentration on tables is practically impossible as the lighter ore particles are washed away with the oil-impregnated water. The entire production of zinc for 1907 was 2500 tons, while at the end of 1908 this district produced a tenth of that amount in a single week. Although some of the leases at Miami are decreasing in

eyes of producers to a fact which previously they had seemed scarcely to realize, that in taking off \$1 per ton for each decrease of 1 per cent. in zinc, occasioned partly by the presence of iron, and in addition deducting a penalty of \$1 per ton for each per cent. of iron in the ore they were being "double crossed." The smelting company making the innovation at Miami foresaw to what it might lead, and abandoned the new base within a few weeks, but other smelting companies continued to make this price until the close of 1908. This may eventually lead to a complete change in the base-price for zinc ores. At present the system of making zinc-ore prices is exceedingly crude.

CONFUSING TERMS

The growing custom of speaking of the ore occurrence in various portions of the district as a sheet or blanket vein is creating a false impression. The sheet or blanket deposits from Oronogo southeast through Webb City, Carterville, Prosperity and Duenweg have no defined side

PRODUCTION BY CAMPS AND STATES

An accompanying table gives the production of the various camps for the first 11 months of 1908 compared with that of the same period in 1907. In table I the first section gives the production of the sheet-ore area from Oronogo southeast to Duenweg; the second section, all territory west and south of the Oronogo-Duenweg area to the State line; the third section, that of the sheet area to the east line of Jasper county; the fourth section, the Lawrence and Green County production; the fifth section, that of Cherokee county, Kansas; the sixth section, the production of Ottawa county, Oklahoma.

Table II is a summary of the larger table, giving the production of Missouri by counties and the total production of the district by States. An approximate reduction to spelter would give the following results: Missouri, 98,326 tons; Kansas, 9724 tons; Oklahoma, 3639 tons.

THE PRODUCTION FOR FIFTEEN YEARS

In only the two preceding years does

ton and lead \$14.20 per ton lower than in 1907, and the district lost over \$5,000,000 in the value of its possible output. The average zinc and lead prices were lower than during the preceding four years.

ZINC ORE PRICES DURING 1908

Zinc ore sold at \$39 per ton the first week of 1908, an advance of \$3 per ton over the closing price of 1907. In two weeks it jumped to \$42.50 and the following week to \$44 per ton. Beginning February at \$42 it declined to \$40, and \$39, then rose to \$40, \$41, \$40.50, \$40, and stood at \$39.50 for three weeks. The two last weeks of April and the first half of May it was \$39, the last half of May \$38, and throughout June it fluctuated between \$36.50 and \$37.75. During all of July and the first week of August the price was stationary at \$38, advancing to \$39, \$39.50 and \$40 at the end of August. September marked a range from \$39.50 to \$41. In October it declined again, opening at \$40.50, dropping to \$39.50 and then to \$39. November opened at \$40, going up to \$41, \$43 and to \$45 at its close. The first week of December the high price was \$46.50, the next week \$47, and the third week \$46.50.

LEAD ORE PRICES DURING 1908

Lead ore brought \$45 per ton the first week of 1908, \$5 higher than the closing week of 1907. It advanced to \$47, and then to \$50, at which price it stood for three weeks, then to \$50.50, \$52 and \$52.50, closing February at \$52. During the first two weeks of March it was \$50 and the latter two weeks \$52 per ton. In April it was \$54 the first week and \$55 the rest

NOTE.—The output of Kansas is from Cherokee county, and of Oklahoma from Ottawa county.

walls, and, as the ore is found in horizontal layers between beds of chert, it is both a blanket and a sheet occurrence. In some of the Spring City mines the ore occurs in layers, but as the deposits have well defined vertical side walls they are not true sheet deposits, though the ore occurring in a channel form has been followed across country for distances as great as half a mile. The ore west of Joplin, discovered by drill during 1907, indicates a wide extent to the mineralized area, but the ore does not form a sheet deposit, for although very little prospecting was done in that part of the district during 1908, enough work was done to indicate that there are no layers of ore. The deposit is a highly disseminated orebody differing only from the disseminated lens deposits of Chitwood in being more regularly spread over a given area. Present developments point to this ore occurrence as a connecting link between the lens deposits, several of which are being mined in this new area, and the sheet deposits. These orebodies will probably be as expensive to mine as the thinnest sheets in the sheet-ore area.

the tonnage of lead shipped exceed the shipments during 1908, but in zinc tonnage the five previous years exceed 1908. The combined value of the lead- and zinc ore production during the four preceding years is greater than that of 1908.

Table III gives the zinc and lead shipments for the last 15 years and also the combined value of both ores. It shows the rise of the Joplin district from hand-jig camps to a district rapidly adopting every method for increasing the output of the mines and every known method of making the mill extraction greater. The four years previous to 1898 illustrate the old hand-jig district. In 1898, owing to the swift rise in metal prices, the mining and milling methods began to be modernized. Since then the advancement in methods of mining, hoisting, milling and even in the marketing of the ore has been wonderful.

HIGH AND AVERAGE PRICES

Table IV, giving the high and average price of zinc and of lead ore for the last 15 years shows the effect of the panic on ore price. Zinc averaged \$9.32 per

of the month. In May the price advanced from \$55.50, to \$56, to \$57, to \$59, and finally to \$60.50, and in June it continued from \$61.50 to \$62.50, to \$64, to \$66. Then the decline in the price of pig lead began to decrease the lead-ore prices to \$62 and \$61, \$60 for two weeks, then up a little again, \$61, \$63.50 two weeks, back to \$61.50, and finally to \$60 at the end of August. September opened at \$59, declined first to \$58, and then to \$57, and closed at \$55.50. In October the price was \$54, \$55, \$54 and \$56. It went up again to \$58 for the first week and \$60 for the second week of November, dropping back to \$55 and \$54 at the close. In December the price dropped to \$53, then to \$51 and during the third week to \$50 per ton.

Zinc Mining in Wisconsin in 1908

By J. E. KENNEDY

Mining in the Wisconsin district experienced a year of depression, as did all other lines of industry, in the year 1908. Compared with the results attained in 1907 there were few new properties opened up. Many concentrators were idle at all periods, yet it is a significant fact that the ore production of 1908 was, nevertheless, the largest this district has ever made. The total shipment of zinc ore reported to Dec. 26 (57,472 tons), exceeded the smelter figure for the entire year of 1907 by 4461 tons. The production of lead ore, though insignificant in amount, increased 100 per cent.; the total shipment reported to Dec. 26 (5393 tons) exceeded the total of last year by 2786 tons. The shipment of pyrites up to Dec. 26 (2536 tons) exceeded the total of 1907 by 2305 tons.

PRICES OF ZINC ORE

At the very beginning of the year zinc-ore prices started upward from the low-water mark reached in December, 1907. By the end of January the base price for 60-per cent. zinc had advanced to \$40 per ton. Many companies which had shut down were induced to resume by this rally in prices, but before these were well under way again a reaction in the market set in, the downward trend continuing until June, when the base price had landed back to \$32 per ton. In spite of low prices for 60-per cent. zinc, shipments steadily increased. The Mineral Point Zinc Company re-entered the competitive field for low-grade ores in April; the Platteville Separating Company began buying about the same time and the Joplin Separator Works, at Galena, was also active. The increased competition for low-grade blende advanced the price heretofore paid for this ore. The market improved during July, August and Sep-

tember and the monthly average shipment during the last six months increased 60 per cent. over the first half of the year.

ZINC CONTENT

The metallic content of zinc shipped was considerably greater than in 1907. During the first three months of the year there was little or no demand for the lower grade ore. The Mineral Point Zinc Company was practically out of the open market from December, 1907, to April, 1908, and other buyers of low and intermediate grades were restricted to limited purchases during this time. Aside from an increased tonnage from roasting and magnetic separating plants, the electrostatic separator, at Platteville, has been turning out a product assaying between 55 and 60 per cent. metallic zinc.

PRODUCTION BY CAMPS

While there are 18 different camps and shipping points in the district, the bulk of the output has come from Platteville, Benton, Hazel Green, Highland, Cuba City, Linden, Rewey, Harker, Livingston, Galena and Mineral Point. It has been the older camps, and, with few exceptions, the older mines which have been producing the ore. Benton and Cuba City developed exceptionally rich bodies of sheet ground. The individual production of many mines was materially increased by better methods of operation; labor, moreover, was plentiful and more efficient.

NEW DEVELOPMENTS

An important point was the completion and successful development of the electrostatic separator at Platteville, by the American Zinc and Lead Smelting Company, operating locally as the Platteville Separating Company. Blende concentrate assaying between 20 and 50 per cent. metallic zinc is bought in the open market. The accompanying pyrite is separated from the blende and recovered as a by-product, assaying between 42 and 48 per cent. sulphur, for the manufacture of sulphuric acid. In the development of the process the original Huff machines were largely changed and improved upon. A constancy of current has been developed which assures a permanent success for the process. During the last three months the plant has been averaging 70 tons per day; its ultimate capacity will only be limited by the average amount of raw ore available.

Nineteen properties were equipped with concentrators during the year; eight of these plants were begun in 1907 and five were second-hand mills. Two new roasting and magnetic separating plants were built. Foundations were laid for a Sutton, Steele & Steele dry-process mill, at Platteville, but construction was deferred

until the spring of 1909. Twenty-five sinking plants were erected.

INVESTMENTS

Comparatively little capital was invested in new enterprises. Shares of stock in undeveloped properties were unsalable. The event of the year was the consolidation of the Empire, Acme, Royal and Mitchell Hollow properties, at Platteville, into the Wisconsin Zinc Company, subsidiary to the American Zinc and Lead Smelting Company. The Picher Lead Company purchased the D. D. C. mine, at Rewey, to furnish raw concentrates to the Joplin Separator Works at Galena, a roasting and magnetic separating plant. The Mineral Point Zinc Company bought additional mineral lands at Highland and Benton. A few other sales of minor importance were made.

PROSPECT FOR 1909

The average weekly output of zinc ore during 1908 was 1000 tons. During November and December the production had increased to 1500 tons weekly. With an open market for all grades of ore and the base price for 60-per cent. zinc ore above \$40 per ton, the mines already opened up will yield in 1909, 2000 tons weekly.

Tin

This metal is not produced in the United States, but we use 40 to 50 per cent. of the world's production, which is made chiefly by Malaya, the Dutch East Indies, and Bolivia. In 1907 the importation into the United States was 82,549,000 lb. In 1908 the statistics will probably show about 75,000,000 lb. The price suffered heavily. In June, 1907, the average was 42½¢, New York. The average for the year was 38.16¢. The average for 1908 was about 29½¢. January, 1908, showed the lowest monthly average, viz.: 27½¢. The failure of tin to make more of a recovery appears to be due to continued large production. At the beginning of the year the prognostications in Malaya were for an extensive suspension of mining. Many of the corporations did indeed suspend, but as in the case of zinc mining at Joplin, the miners went back to old diggings and made a new production by primitive methods.

The Tin Market at New York
in 1908

In sympathy with all other metals, the consumption of tin in this country suffered considerably during 1908. For this reason, the statistical position became

pendent upon the course which the metal takes on the London exchange, with such exceptions as are brought about by a scarcity or a corner in spot material, when premiums to a larger or smaller extent are exacted.

The market at the beginning of the year showed a firm undertone, and prices were quoted at about 26½@27c. for spot delivery. Spot material remained scarce throughout January and a premium of 1½@¾c. per lb. was paid for the same.

During the first half of February, under the lead of the London market, prices advanced to 29¼c., then declined to 28c., but rallied to 29c., and remained on about that level for the remainder of the month.

the end of May, spot tin was quoted at 28¾c. in this market.

In July the low point of the year was reached, and sales took place at 27¼c. The better feeling prevalent in the copper market toward the end of July and the beginning of August had a sympathetic effect on tin, and prices advanced to 31c. for spot material.

August and September witnessed again a gradual decline in prices brought about by an entire absence of interest among consumers. Quotations were 29½c. at the end of the latter month.

In October, tin remained fairly steady at around 29½c.; it advanced during the month of November to 30½c. per pound; but declined again in December, owing

more unfavorable from month to month, and at the end of the year visible supplies had increased to about 20,000 tons, as against about 13,000 tons in December, 1907.

The market for tin is influenced entirely by the operations of a few large concerns in London, and while 1908 did not witness the spectacular gyrations of 1907, it was nevertheless characterized by severe fluctuations up or down, accordingly as the bulls or bears had the upper hand. The domestic market is de-

The announcement by the Dutch Government at the beginning of March of a reduction in the sale of Banka tin during 1907 led to excited speculation in the London market, where prices advanced considerably. Quotations at that time were established at 30½c. in the domestic market. March showed still further advances, and at the beginning of April quotations were about 31¼c. Until the middle of May, prices remained on this level, when a bear attack in the London market brought about a severe decline. At

to its unfavorable statistical position which became public at the beginning of the month, to 29c., and closed at 29 cents.

The Iron and Steel Industry in 1908

A Year of Deep Depression and Small Demand with Only Gradual Recovery. An Attempt to Revise Law of Supply and Demand

PIG IRON 15,828,000 TONS

The record of the iron and steel industry in 1908 is one of general and extreme depression followed by a slow and gradual recovery which promises well for the future, but is not yet so fully established as to warrant us in saying that a new prosperity is yet in sight. Another year will be needed, in all probability, to restore conditions fully and place the industry on a solid basis.

Iron and Steel Production

By FREDERICK HOBART

The short and sharp curtailment of the closing months of 1907 put the productive capacity of the United States on a basis lower than had been seen for at least eight years. The conditions were different

from those of any previous period of depression. The dominating influence of the United States Steel Corporation had been exercised only in prosperous times, and it had now to face the reverses which had been brought about by a period of overtrading and too extended credits. The way in which this was done finds no precedent in former years. Through an adroit use of its influence in uniting with

it the larger independent producers the Steel Corporation succeeded in holding the trade to a policy of maintaining prices in the face of a lessened demand. This defiance of the law of supply and demand was maintained throughout the year, only some small reductions being made in a grudging way and at a time when they they were of the least effect. The result is apparent to those who study the operations of the year. Recovery, which has come slowly, might, it is believed by many, have been hastened by free concessions which would have encouraged the investment of capital in construction, by offering the advantages of cheaper material. It was in this way that recovery was started in former periods of depression with undoubted success.

A disturbing element came in during the latter part of the year in the form of the tariff-revision movement. To say nothing of the actual merits of the case, the conflicting testimony submitted at Washington confused the public mind. From present indications it is highly probable that reductions in duties will be made, and that iron and steel products will be picked out for such decreases. It is not probable that this will seriously injure producers or the trade; but the expectation of changes caused a halt for the time being.

The course of production in 1908, as compared with previous years, is shown below:

IRON ORE

The production and consumption of iron ore showed a very considerable decrease from the high level of 1907, as might have been expected. The cutting down of operations was sharp and sudden—more so, perhaps, than in any preceding period of depression, since a much larger proportion of the output is under a unified control than ever before. As in the previous year, Lake Superior ores furnished the raw material for 75 to 80 per cent. of the pig-iron production.

The estimated output of iron ore is as follows, in long tons, compared with the output of the preceding year:

	1907.	1908.	Changes.
Lake Superior.....	42,245,070	25,927,000	D. 16,318,070
Southern states.....	7,595,000	6,400,000	D. 1,195,000
Other states.....	3,125,000	1,875,000	D. 1,250,000
Total production.....	52,965,070	34,202,000	D. 18,763,070
Add imports.....	1,222,168	675,000	D. 557,168
Total supply.....	54,187,238	34,877,000	D. 19,307,238
Deduct exports.....	278,208	310,000	I. 31,792
Balance.....	53,909,030	34,567,000	D. 19,339,030

In the imports and exports the month of December is estimated.

In this statement no account is taken of stocks on hand, for the reason that it is impossible to obtain any exact figures concerning them. The stocks on Lake Erie docks at the close of navigation in 1908

showed an increase of 1,055,000 tons over the preceding year; but a considerable part of this is under contract and awaiting transportation. Stocks in furnace yards are believed to be smaller than they were a year ago. In 1907, owing to the sudden stoppage of many furnaces, there was a large accumulation of ore at furnace stockyards; this year the piling up of stock has been at the Lake docks instead. The larger stocks there may be regarded as a provision made against a possible increase in furnace activity before the opening of navigation next spring.

Ports.	RECEIPTS.		STOCKS.	
	1907.	1908.	1907.	1908.
Toledo.....	1,314,140	680,553	518,645	590,925
Sandusky.....	83,043		44,546	36,079
Huron.....	971,340	213,377	415,730	458,158
Lorain.....	2,621,025	2,286,388	366,271	426,274
Cleveland.....	6,495,998	4,240,816	1,281,335	1,458,392
Fairport.....	2,437,649	1,518,961	523,981	835,821
Ashtabula.....	7,521,859	3,012,064	2,056,820	2,293,531
Conneaut.....	5,875,937	1,798,631	1,090,774	1,296,675
Erie.....	2,294,230	828,602	632,210	730,530
Buffalo.....	5,580,438	2,835,099	435,407	315,148
Total.....	35,195,758	20,414,491	7,385,728	8,441,533

Allowing for the probable increase in stocks the consumption of ore per ton of pig iron made in 1908 was approximately 1.08 tons, or a little higher than in previous years.

Lake Superior Ores—The statistics of Lake Superior shipments are so closely kept that it is possible to give definite figures, especially as water shipments close early in December. The only estimate required this year is of the rail shipments, part of which are made during the winter. The shipments of Lake ore, by ports, were as follows, for two years past, in long tons; with the rail shipments added for 1907, and an estimate of them for 1908:

Port.	1907.	1908.
Escanaba.....	5,761,988	3,331,502
Marquette.....	3,013,826	1,487,487
Ashtabula.....	2,437,672	2,513,670
Superior.....	2,440,386	3,564,030
Duluth.....	13,415,977	8,808,168
Two Harbors.....	8,188,906	5,702,237
Total water.....	41,288,755	25,427,094
Rail.....	956,315	500,000
Total.....	42,245,070	25,927,094

The distribution by ranges in 1908 is not yet complete. Escanaba and Marquette are the shipping ports for the Marquette and the Menominee ranges, Ashland for the Gogebic. Two Harbors takes the ore from the Vermilion range and a part of the Mesabi; while the docks at Superior and Duluth are supplied entirely from the Mesabi range. The rail shipments come from all ranges; they go to Zenith furnace at Duluth, to the furnaces at Marquette, Gladstone, St. Ignace and other points in Michigan and Wisconsin.

The season shipments to furnaces from Lake Erie ports, to which about 80 per cent. of the Lake ore goes, and from which it is distributed were as follows:

	1907.	1908.
Ore on docks, May 1.....	1,976,988	5,180,300
Receipts for the season.....	35,195,758	20,414,491
Total.....	37,172,746	25,594,701
Shipments to furnaces.....	29,787,018	17,453,258
Stock on docks, Dec. 1.....	7,385,728	8,441,533

The decrease in shipments to furnaces was 12,333,760 tons; and the increase in stocks on docks Dec. 1 was 1,055,805 tons. This is a sufficient reserve to provide for any probable contingency. The distribution of the stocks held Dec. 1 among the ports, and the receipts of those ports for two years were as follows:

The 20 per cent. of Lake ore which does not find its way to Lake Erie ports, goes chiefly to Chicago and vicinity for the furnaces of the Illinois Steel Company and others, and lately for the great new furnaces of the Indiana Steel Company at Gary.

Other Ore Production—The production in the Southern States is the most important after that of the Lake Superior region. It is, as a rule, closely regulated by the activity of the furnaces. The control of the mines by the iron-making companies and the proximity of the mines to the furnaces makes it unnecessary to accumulate stocks, as is done with the Lake ores, which have to be carried from 500 to 1000 miles by water, over routes which are closed by ice for five months of the year.

In the East, New York, Pennsylvania and New Jersey are the larger producers, in the order given. In all of them there was a considerable reduction in output. The same condition prevailed in the widely scattered iron-ore regions of the West.

General Conditions—The depression of the year did not stop preparations for an increase in the production of iron ore. Extensive operations are being carried on in stripping and preparing for mining on the lands of the United States Steel Corporation on the Mesabi range in Minnesota. In the Southern field all the large companies have made arrangements to extend their mining operations, and to improve them by the use of new machinery and appliances. In New York several new mines have been opened and some old mines reopened. The universal anticipation seems to be for a greater demand for ore, which must be met.

A noticeable feature in all this new development work is the tendency to use lower grade ores. Even on the Lake ranges ores are taken into consideration which would formerly have been passed by. This is a significant feature.

The imports of iron ore during the year were chiefly from Cuba, and were used in the Maryland Steel Company's furnaces near Baltimore, and in others near the coast. The exports were chiefly to Canada.

Manganese Ore—The imports of manganese ores for the 11 months ended Nov. 30, the latest complete figures, were 188,526 long tons in 1907, and 170,662 tons in 1908; a decrease of 17,864 tons.

Limestone Flux—The production of limestone and dolomite for use as flux in iron blast furnaces in 1908 is estimated at 9,650,000 long tons, a reduction of more than 6,000,000 tons from the previous year. Dolomite is used chiefly at the Alabama furnaces, limestone being the usual flux elsewhere.

PIG IRON

The sharp contraction in pig-iron production which marked the close of 1907 continued well into 1908. There were, of course, many changes in the list of active furnaces, but only small increases in their aggregate capacity until well on toward the middle of the year. From that point an improvement began, which continued slowly but steadily, the second half of the year showing a substantial gain over the first.

For the first half of the year the American Iron and Steel Association has collected the full figures. Estimating the second half on the basis of the capacity of the active furnaces, we have the following production for the year. The comparative figures for 1907 are, of course, the corrected returns. The figures are in long tons:

	1907.	1908.	Changes.
First half . . .	13,478,044	6,918,004	D. 6,560,040
Second half . .	12,303,317	8,910,000	D. 3,393,317
Total . . .	25,781,361	15,828,004	D. 9,953,357

The decrease in 1908 was, therefore, 38.6 per cent., the greatest proportional loss ever shown in one year.

Assuming that the division of the iron, according to the uses for which it was intended, was approximately the same in the second half of the year as in the first half, for which we have official figures, we find that the production of 1908 compares with that of the preceding year as follows, the figures being in long tons:

	1907.	1908.
Foundry and forge iron . . .	6,397,777	4,203,000
Bessemer pig	13,231,620	7,754,000
Basic pig	5,373,219	3,380,000
Charcoal iron	437,397	299,000
Spiegel and ferro	339,348	192,000
Total	25,781,361	15,828,000

It is probable that this apportionment is not quite correct, as the increase in the second half of the year was somewhat greater in the steel-making irons—especi-

ally in basic pig—than in foundry and forge iron.

On June 30, the middle of the year, there were 168 furnaces in blast. On Dec. 1 the number had increased to 220, and was about 225 on Dec. 31. On June 30 there were 24 new furnaces under construction and 17 were being rebuilt. Only a few of the new furnaces were completed at the end of the year, but these included the first group of the great new furnaces at Gary.

The consumption of pig iron in the United States in 1908 was, approximately, as follows:

Production	15,828,000
Imports	89,000
Total supply	15,917,000
Exports	46,000
Approximate consumption	15,871,000

This shows an average yearly consumption of 406 lb. per capita. The imports and exports were both light.

The pig-iron production for 10 years has been as follows:

1899 . . .	13,620,700	1904 . . .	16,497,083
1900 . . .	13,789,242	1905 . . .	22,992,380
1901 . . .	13,878,354	1906 . . .	25,307,391
1902 . . .	17,821,307	1907 . . .	25,975,941
1903 . . .	18,009,259	1908 . . .	15,828,000

The production of 1908 was the smallest for eight years; it was rather less than half of our actual capacity for making iron.

STEEL PRODUCTION

No figures are available as to the production of steel for any part of the year, and only approximations can be made, based on the production of pig iron. It is estimated that the output of bessemer steel in 1909 was about 7,200,000 tons; of basic steel 7,100,000 tons; and of other steels 50,000; making a total of 14,350,000 tons, or a decrease of about 9,010,000 tons from the previous year.

No figures are available for the output of finished material, but the reduction was undoubtedly on parallel lines with the falling off in iron and steel. The greatest decrease was in rails and track material; the least in structural iron and steel.

CHANGES AND CONSOLIDATIONS

No important changes are recorded during the year, and nothing so important as the transfer of the Tennessee Coal, Iron and Railroad Company in 1907 occurred. There was some exchange of properties among the subsidiaries of the Steel Corporation, but these did not change the general management. In December there was an important transfer of stocks of the Colorado Steel and Iron Company, which indicated that the Gould interests had parted with their control of that company. The new interest in the company is reputed to be either the United States Steel Corporation, or parties closely allied with it. These reports have not been confirmed, but are considered probable. Under present conditions it is not

likely that the Steel Corporation would openly assume possession of this important Western concern. Its management on a friendly basis would, however, be a valuable asset.

METALLURGICAL PROGRESS

Metallurgical changes during the year have been comparatively few. The great Gary plant of the Steel Corporation has begun work, two of its blast furnaces having been started in December. The most important feature of this plant is the use of blast-furnace gases for the production of power on a scale much larger than has heretofore been attempted. Progress was made in the use of the Gayley dry-air blast, and an extended course of experiments proved that its advantages when applied to the bessemer converter were quite as great as with the blast furnace.

IMPORTS AND EXPORTS

The values of the imports and exports of iron and steel, including machinery, in the United States for the 11 months ended Nov. 30 are reported as follows:

	1907.	1908.	Changes.
Exports . . .	\$182,008,912	\$139,981,651	D. \$43,157,251
Imports . . .	\$6,740,291	\$18,247,668	D. \$11,492,623

The decreases were 23.7 per cent. in exports, and 50.3 per cent. in imports. The decrease in exports was in almost all branches, the structural steel and wire trades best maintaining their sales abroad. In imports the greatest decrease was in pig iron and in billets and other half-finished material, considerable quantities of which were brought in during the previous year under the stress of active demand.

At different times in the past we have heard a great deal of the possibilities of foreign trade in iron and steel products. This trade was to act as a balance wheel, maintaining production at an even level when the home demand was slack. Much was said of organizations promoted by the larger steel companies for the purpose of handling and extending sales abroad. In the present period of depression, however, these agencies did not work, apparently, as shown by the figures given above, exports having decreased to as great an extent as the home production.

The fact is that, in all the talk about foreign trade, no account was taken of the fact that under modern conditions a trade depression is not confined to one important country. It extends to others in greater or less degree, even spreading through the entire commercial world. When we have a large surplus to sell abroad, the demand there has fallen off, almost on parallel lines to our own. Other countries may be willing to buy our products at a low rate, but the purchasing and consuming capacity has been reduced. The balance-wheel theory failed entirely.

when it came to be tested, because there was little foreign demand to operate it, and low prices offered could not start the wheel.

In Great Britain, the chief exporting country, the foreign trade showed nearly the same course. The exports of iron and steel for the 11 months ended with November were 11 per cent. less in quantity this year than in 1907. While the decrease in domestic demand has been less marked than in the United States, foreign sales have shown even a greater decrease. Evidently the world was not a free buyer in 1908.

Germany alone among the important iron-making nations had a small increase—7 per cent.—in its exports. This was gained at the expense of producers by the large syndicates, which have sold abroad at such sacrifices that there have been strong remonstrances from a number of the constituent companies. Moreover, the gain in exports was chiefly in pig iron and in half-finished products. British, Belgian and French iron-masters took advantage of the syndicate policy to put in stocks of pig iron and steel billets at prices lower than their own cost of production. These crude products are finished in their own mills. Whether such sales of material are advantageous to German makers in an open question.

We do not decry the value of foreign trade, which may be a valuable asset of manufacturers when well established. It cannot, however, be established on short notice, nor can it be relied on any more than home trade in times of depression. And it may—as in the case of Germany—be acquired at a cost beyond its value.

FOREIGN COUNTRIES

European countries report a depression in the iron and steel trades parallel to our own, though not quite as great in amount. The British statements are unusually incomplete this year, but such as are available indicate a decrease of from 10 to 15 per cent. in iron and steel production. Exports for the year decreased considerably, as above noted.

In Germany pig-iron production for 11 months decreased nearly 10 per cent. and the market is reported extremely weak under the pressure of large unsold stocks. In part the overproduction thus indicated is said to be the result of the extended use of blast-furnace gases for power. Many furnaces have been kept in blast because the power was needed for other parts of the works, thus indicating one of the drawbacks of the system. The Steel Syndicate maintains its position so far, but the two important pig-iron syndicates have gone to pieces, with disastrous results to prices.

In other European countries production has declined, and everywhere the markets are in weak condition. As the European depression followed our own, so the recovery seems to be slower in coming.

The Iron and Steel Markets

The markets for iron and steel at the beginning of the year were in the condition of deep depression. The shock of the financial depression which began in October, 1907, was still too recent for recovery to begin, and it was not for some months that the trade was on its feet, so to speak; and not until nearly the end of the year was there a pronounced tendency to better conditions. Even at the present time recovery is progressing slowly. There is confidence in the future, as is shown by the preparations being made in many quarters to increase production; but this confidence has not yet reached the point of inducing active trade.

The most prominent feature of the year was the control over prices exercised by the large producers through the influence of the supervising committees instituted in December, 1907. These committees were active throughout the year, and their work was effective for the most part. The dominating influence was, of course, that of the Steel Corporation. The motives of this policy and its wisdom—or otherwise—are discussed elsewhere, and it is necessary here only to discuss its immediate effects.

The only really open markets for the greater part of the year were those for pig iron, for iron bars and for a few minor products. Pig iron was badly demoralized for a considerable part of the year, and its recovery was gradual and irregular. The business was limited, notwithstanding low prices; but this was due to the fact that so large a proportion of the pig iron made enters into the production of steel, the quotations for which were not materially lowered. Bar iron was an open market, owing to the large independent interests in that branch, and the lowering of prices on that product did stimulate orders and force a reduction in the quotation for steel bars to meet the competition.

The only changes in price made were some small ones in January, and a general "readjustment" in June, which involved reductions of 10 to 15 per cent. in the leading articles of finished steel. These did not have the effect of stimulating trade in any marked degree; and thereafter no material changes were made. It was pointed out by many consumers that there was a wider spread between quotations of pig iron and finished material than had often existed; but these representations had no effect.

The railroads were light customers throughout the year, and their purchases of rails were lighter than for a number of years. In part this was the result of inability to purchase, owing to decreased earnings and difficulties in finance; in part of the still unsettled dispute over specifications, and in part over the question of price. Toward the end of the year some good orders were placed for

locomotives and other equipment, mainly for steel cars. Some good orders for bridge work also came forward. The rail question, however, is still far from a real settlement; and the rail mills enter 1909 with a lighter business on their books than has been the case for several years. In light rails for mining and industrial purposes, on which the price restrictions were removed, owing to the competition of the rerolling mills, there was a good business.

Recently the tariff discussion has had an effect on the markets, chiefly because it has strengthened the tendency to wait developments, and to defer contracting for future requirements until a more settled condition is reached. This question has also been considered elsewhere.

Details of the markets will be found in the following letters, which cover Pittsburgh and Birmingham, the chief primary markets; Chicago, the leading distributing point for the Northwest; and the seaboard markets.

The Alabama Iron Market

BY L. W. FRIEDMAN

Despite the general depression, which struck Alabama hard, continuing through the better part of the year 1908, the aggregate make of pig iron is only 300,000 tons less than in 1907. The depression came on the latter part of 1907, cutting the production down during the last three months to a considerable degree, but the total production for that year showed an increase over the previous year of about 118,222 tons.

The production of pig iron in Alabama for the year reaches a total of 1,405,000 tons, the last month's output a day or two behind official figures. When it is considered that the high-water mark by the month was not reached until November, 141,200 tons, with the first month of the year starting off with 86,000 tons, improving in February and March and then falling back in April to 94,800 tons, thence taking on improvement month by month, the total production can be looked upon with much satisfaction.

The number of furnaces in operation in Alabama varied. There was a good sized accumulation of iron through the first part of the year, but the production was held down and no effort was made to work to full capacity and that condition has not been reached as yet, though the recent depression appears to be a thing of the past.

Alabama iron producers suffered not alone from the general depression, which other districts also experienced, but also from a hard fight with union labor, the United Mine Workers of America in the district declaring a strike. This proved a battle to the finish and in its course there was a considerable falling off in coal and

coke production, causing the iron-masters to make contracts for this supply in other districts, all of which affected the iron production. While by all indications the iron make was maintained during the strike, it was with much difficulty and expense.

The quotations for pig iron in Alabama during the year 1908 ranged between \$11 and \$13 per ton, on No. 2 foundry basis. Recently the \$13 rate became a fixture. On this score there is but little said. Some large-sized sales of iron were consummated during the low-price period, but care was taken by the producers in this section that this business should not interfere with general trade when the conditions improved. One instance is reported where a large bulk of iron was sold during the quiet period, but the stipulation was that the product would be held in yards at furnaces subject to delivery, but there was to be no delivery while the prices were down. When the iron went up, the speculation proved a good one and at the same time did not interfere with the general market.

Alabama witnessed considerable improvements in blast-iron furnaces during the year. But one concern fell by the wayside, the Southern Steel Company, while some of the progressive companies made deals whereby they took in other properties. The Birmingham Coal and Iron Company acquired the properties of the Tecumseh Iron Company (an ore-mining company), and completed and put in blast its new furnace at Vanderbilt, near Birmingham. The Tennessee Coal, Iron and Railroad Company made extensive improvements about blast furnaces and started work on big improvements in the steel plant. The Woodstock Iron Company put in shape one iron-maker and repaired another, besides putting in operation mining and other properties. The Sloss-Sheffield Steel and Iron Company practically rebuilt one furnace and has a force of men improving another. Other concerns made improvements despite the depression.

The raw-material supplies were given some attention and since the general quiet has been passing off the improvements have been worked on with vigor, so that the new year has started in with great expectations.

The depression, the placing of improvements and other reasons, affected the steel production in Alabama. The big plant of the Tennessee Coal, Iron and Railroad Company at Finsley was the only institution of the kind in the State that worked through the year. With the exception of the last week in the year there was no interruption in this industry. The plant produced more than 38,000 tons of blooms in one month, and made 32,424 tons of rail. The average was kept up pretty well toward the latter part of the year. The aggregate production will show a falling off, as there was a cessation of operation

at the big plant for some time. There was but little accumulation at the steel plant and to meet any kind of a demand it will be necessary to have a steady run.

The Chicago Iron Market

By E. MORRISON

Except for two or three large transactions made at low points in the market, the history of the pig-iron market in Chicago for the year 1908 is a record of small buying for needs not more than three months away. The year began in depression. Prices fell gradually as it became apparent that no general revival of business was at hand. Sales of carload lots to 200 or 300 tons became the rule, and May saw iron decline from \$18@18.25, the January price for Northern No. 2, to \$17@17.50. Southern from \$13@13.50 Birmingham (\$17.35@17.85 Chicago), in January had dropped to \$12 Birmingham, in the open local market. One large sale of about 50,000 tons was made in February at \$11 Birmingham, and this transaction weakened the market greatly, the average melter concluding from it that general reduction in prices would follow.

The Spring depression lasted into June, when another sale of nearly as much tonnage was made of Southern at \$11. There was a wave of buying for a brief time, and the market strengthened slightly. Southern was prevented from sagging below \$11.50 in the open market and continued to rise slowly until December, when it brought \$13@13.50 (\$17.35@17.85 Chicago). Northern continued depressed, and in September, October and November sold at \$16.50@17, or for less than Southern. This exception to the ordinary relations of the two kinds was largely due to the selling of considerable iron from Ohio furnaces throughout the months named at \$16.50@17, meeting the needs of users of Northern to the disadvantage of local furnaces.

The high and low points in the market for 1908, compared with the high and low points of the preceding year, are shown in the accompanying table.

	1907.		1908.	
	High-est.	Low-est.	High-est.	Low-est.
Lake Superior charcoal	\$28.00	\$25.00	\$24.00	\$19.50
Northern No. 2 foundry	27.00	19.00	18.50	16.50
Southern No. 2 foundry	27.35	19.35	17.85	15.35
Bar iron	1.865c	1.75c	1.65c	1.50c
*Structural material	1.88c	1.865c	1.78c	1.88c

* Beams and channels, 3 in. to 13 in., and angles 3 in. to 6 in. by 1 in. or heavier.

It was the hope of many in the iron business that the national election in November would bring a decided change

in the condition of the market. Immediately preceding the election the market was very weak, but there was no decided change from the election or from any perceptible cause. Very slowly the trend upward became perceptible, however. The last half of the month of December saw a lull in business nearly always experienced in that month, but peculiarly disappointing because of the hopes raised by the gradual strengthening previously of the market.

There was little buying for more than three months ahead of needs at any time during the year and contract-making became restricted to the needs for the current year just before the election. The expansion into more general buying for the future in the last two months of the year rather than any increase in the immediate needs of buyers accounted for the general betterment of the market.

For iron and steel products the market was in general quiet, despite reductions in June from 1.65 to 1.50c. on iron bars and from 1.88 to 1.78c. on structural material. In summer the Western railroads began buying on a large scale in comparison with their purchases in the first half of the year, and they continued to make purchases throughout the last six months. Building projects became important, and the end of the year saw a large tonnage needed for bridge and building operations in sight.

The Pittsburg Iron and Steel Markets

By S. F. LUTY.

Although the depression in the iron and steel trade which began in the last quarter of 1907 continued through 1908 the year was not as bad as the outlook at the opening indicated. This was due to co-operation on the part of the large producing interests. Meetings were held at intervals at which reports on conditions were received and plans for future action decided upon.

The strong position taken by the United States Steel Corporation at the outset in the matter of prices had a great deal to do with preventing a demoralization of the markets. When readjustments were made conditions only were considered, and at no time was the price of a commodity reduced for the purpose of enticing buyers into the market. Chairman E. H. Gary of the Steel Corporation contended that the cutting of prices in a dull period would not induce buying but instead would seriously disturb the situation.

Mill operations in January were unsatisfactory except in the tinplate and wire branches. At the opening of the month the American Sheet and Tin Plate Company had but 52 tin mills on the active list but before the close 154 mills were going. The American Steel and Wire

Company operated its plants at an average of around 70 per cent. throughout the year, starting at over 60 per cent. and closing the year with nearly 90 per cent. of its capacity active. Since the latter part of the first quarter all the large concerns report a gradual increase in production, each month being a trifle better than the previous one.

New business during the year was chiefly for small tonnages, showing that consumers bought only for immediate requirements. Agricultural - implement makers who had placed contracts for the year ending June 30 took all the material ordered and were buyers of large tonnages through the year. The farmers had a profitable season and did not hesitate to place orders for new implements. They were also heavy buyers of fence wire.

Rail buying was disappointing. The tonnage placed all year did not amount

ark, N. J., to Jamaica, L. I., which will amount to \$5,000,000. The Duluth & Iron Range Railroad, a Steel Corporation interest, in December ordered 800 ore cars which are being built by the Standard Steel Car Company, Pittsburg, at its Hammond works. They are of the Summers type and are for delivery in March and April. The 6,400 wheels will be furnished by the Carnegie Steel Company which bought the Schoen Steel Wheel Company's works at McKees Rocks, Pittsburg, in July.

The Newburg & South Shore Railroad of the American Steel and Wire Company late in November placed an order with the Pressed Steel Car Company, Pittsburg, for 275 steel cars and the Birmingham Southern Railroad of the Tennessee Coal, Iron and Railroad Company, bought 160 steel cars. The Pittsburg & Lake Erie Railroad placed orders for 2000 cars, 1500 with the American Car and Foundry

company's contract with the Carnegie Steel Company for billets expired on June 30.

The year opened with a weak pig-iron market and most of the merchant furnaces in the Valleys were closed on account of dull conditions. The highest price of the year was in January and the lowest in October. As soon as the result of the national election was known producers advanced prices \$1 and more a ton, and thereby checked what looked like a good buying movement. This did not deter producers from maintaining firm prices the rest of the year.

Average prices for all sales by months are shown in the accompanying table. The official average of bessemer iron in which only sales of 1000 tons or more are considered was as follows, Pittsburg delivery: January, \$10; February, \$17.00; March, \$17.86; April, \$17.40; May, \$16.92½; June, \$16.90; July, \$16.73; August, \$16.11; September, \$15.00; October, \$15.48; November, \$16.74; December, \$17.40.

The production of pig iron at furnaces in the Pittsburg district and the Valleys for the year has not been compiled.

Merchant furnace interests demanded a reduction in ore prices but at two meetings of ore producers, one on Jan. 29 and the other on Feb. 6 the appeal was ignored and old prices reaffirmed. The lake ore shipping season did not open until June 1 and a week later producers cut the price 50c. a ton, the season's new prices being as follows: Mesabi non-bessemer, \$3.50; Old Range non-bessemer, \$3.70; Mesabi bessemer, \$4.25; Old Range bessemer, \$4.50. These prices were guaranteed until May 1, 1909. The lake ore shipments for the short season of 1908 amounted to 25,430,544 tons.

When the Pittsburg Steel Company started four of its new open-hearth furnaces in July it bought 8000 tons of basic iron from the Midland furnace at a low price. Other small lots were purchased until Oct. 19 when it entered into a five-year contract with the Penn Iron and Coal Company, operating a furnace at Canal Dover, O., for 6000 tons a month, or a total of 360,000 tons. The price was on a sliding basis. The Standard Sanitary Manufacturing Company and the Westinghouse interests were large purchasers of pig-iron during the year.

The foundry pig-iron producers held several meetings early in the year for the purpose of devising means for preventing a decline in prices but all were unsuccessful. It was found to be impossible to maintain prices and late in April the pig-iron market was thrown wide open.

While the movement of the United States Steel Corporation and other large steel interests for the maintenance of prices was not an entire success it had the effect of preventing general demoralization.

The first readjustment of prices oc-

to much more than 1,500,000 tons against about 3,600,000 tons in 1907 and almost 4,000,000 tons in 1906. Difference with the railmakers over specifications and also a lack of funds are assigned as reasons for failure to buy more liberally. Early in the year the Pennsylvania Railroad reserved 147,000 tons and on Feb. 6 announced that it had placed 55,000 tons. The railmakers, however, rejected this order on account of the specifications. This road got through the year with less than 10,000 tons of rails which were purchased from the Cambria Steel Company and used for experimental purposes. In December this road entered the market with an order for 135,000 tons for 1909 delivery. Other lines placed orders for smaller tonnages. The large systems are figuring on their requirements and are expected to enter orders early in 1909.

Late in the year railroads were large buyers of track material and bridge work, also rolling stock and other equipment. In November the Pennsylvania Railroad placed an order with the Westinghouse Electric and Manufacturing Company for the electrification of its system from New

Company and 500 with the Standard Steel Car Company.

Structural steel contracts were confined to small tonnages chiefly, but there were a number of from 2000 to 3000 tons. The largest called for 13,500 tons for the Beaver bridge of the Pittsburg & Lake Erie Railroad and 12,000 for the new Oliver building in Pittsburg.

Work on the steel plant and blast furnaces being built at Aliquippa, a few miles below Pittsburg, on the Ohio river, by the Jones & Laughlin Steel Company which was stopped when the depression began late in 1907 was not resumed, but likely will be early in the new year. The new open-hearth steel department at the Ohio works, Youngstown, of the Carnegie Steel Company, was finished early in the year and put in operation. The Youngstown Sheet and Tube Company's two new blast furnaces were completed and put in blast in November. The Pittsburg Steel Company, the large independent wire interest, completed eight open-hearth furnaces at its plant at Monessen, about 40 miles from Pittsburg, in June and four were started in the following month. This

curred on Jan. 6 when tinplate was cut from \$3.90 to \$3.70 a box; black sheets, \$2 a ton from 2.60c. to 2.50c. for No. 28 gage; galvanized sheets, \$4 a ton, from 3.75c. to 3.55c. for 28 gage; blue annealed sheets, 5c. per 100 lb., making new prices as follows: Nos. 10 and heavier, \$1.80; Nos. 11 and 12, \$1.85; Nos. 13 and 14, \$1.90; painted corrugated roofing 10c. a square, from \$1.85 to \$1.75; galvanized corrugated roofing, 15c. a square, from \$3.25 to \$3.10. It was explained that these cuts were not made to induce buying, but were on account of the reduced cost of raw material.

A meeting of the principal bar-iron producers was held in Pittsburgh on Jan. 7 at which prices for Pittsburgh and Eastern shipment were reduced \$1 a ton to 1.55c. Pittsburgh, and for Western shipment \$4 a ton to 1.40c. Pittsburgh.

A practical reduction in the price of billets was made in March when the mills agreed to divide the freight of finishing mills located outside of Pittsburgh when the rate was from \$1 to \$3 a ton.

At a meeting of steel interests held in New York on June 9 a readjustment of prices was decided upon. Billets were cut \$3 a ton, from \$28 to \$25; sheet-bars and tinplate-bars, \$2 a ton, from \$29.50 to \$27.50; structural material, a general cut of \$2 a ton; shapes, from 1.70 to 1.60c.; plates, \$2 a ton, from 1.70 to 1.60c.; wire products, 10c. per 100 lb.; wire nails, 10c. a keg, from \$2.05 to \$1.95; merchant-steel pipe, two points, or \$4 a ton. Later wrought-iron pipe prices were reduced one point, or \$2 a ton, by manufacturers who did not attend the steel meeting.

On June 1 the price of steel bars was cut \$4 a ton, from 1.60c. which had been the price for two years, to 1.40c. On June 11 bar-iron prices were reduced to 1.40c. Pittsburgh, and to 1.35c. for Western shipment.

The season's cotton-tie price was fixed in April at 85c. a bundle, the rate that ruled in 1905 and 1906, and a cut of 10c. a bundle from the 1907 price. Over 2,000,000 bundles, or 40,000 tons, were bought soon after the price was arranged.

On Jan. 22 the price of light rails was reduced \$2 a ton but the new price was immediately shaded. Re-rolling mills cut the price of the large producers from \$2 to \$3 a ton all year.

The established prices on finished material were not strictly adhered to at all times. In the summer plates were cut about \$2 a ton. Sheets also were shaded in some extremely dull periods and in September and October tinplate was shaded from 5 to 10c. a box. In the last two months of the year prices in all lines were firmly held.

WAGE ADJUSTMENTS

Although dull conditions prevailed throughout the year there were no particularly severe wage reductions. Outside of the mills governed by the annual wage

scale of the Amalgamated Association of Iron, Steel and Tin Workers there was no concerted action in the matter of wages. In a few foundries and machine shops wages were readjusted and the reductions were accepted by the workmen without protest.

A largely attended meeting of merchant blast-furnace interests was held at Youngstown on Jan. 21 for the purpose of considering the advisability of reducing the wages of blast-furnace workers 20 per cent. After a thorough discussion it was decided to make no change as a cut might result in a further depression in pig-iron prices.

Bi-monthly adjustments under the Amalgamated Association scale were as follows:

January—Bar iron average, 1.55c., a decline of 0.05c. compared with previous settlement, puddlers receiving \$6.37½ a ton, a cut of 12½c. Sheets, average \$2.40 same as previous settlement, workers continued to receive 2.6 per cent. above base. Tinplate, average, \$3.70 a box and workers continued to receive 6 per cent. above the base.

March—Bar iron average, 1.45c., puddlers receive \$6.12½, a cut of 25c. a ton. Sheets, average 2.30c., the base, and workers' pay 2.6 per cent. Tinplate, average \$3.50 a box, and workers cut 4 per cent.

May—Bar iron average, 1.45c. No change, puddlers pay continuing at \$6.12½ a ton. Sheets, average 2.30c. No change. Tinplate average, \$3.40 a box, the base, and workers' pay cut 2 per cent.

July—Under new scale. Bar iron average, 1.35c. and puddlers' pay \$5.37½ a ton, a cut of 75c. a ton. Sheets, at new base, a cut of about 2 per cent. Tinplate, at new base, a cut of about 5 per cent.

September—Bar iron average, 1.30c. and puddlers' pay cut to \$5.25 a ton. Sheets and tinplate no change.

November—No change in the three branches.

The annual convention of the Amalgamated Association opened in Youngstown on May 5 and continued in session for two weeks. No changes were made in the wage scales. A conference was held at Cambridge Springs, Penn., June 1 with the Western Bar Iron Association. A stiff reduction was demanded, but workers refused and conference adjourned without a date. Amalgamated committee met officers of the Republic Iron and Steel Company on June 22 and could not agree on new scale. A conference was held on June 26 with the American Sheet and Tin Plate Company. The result was a complete readjustment of the advantageous scales enjoyed by the workers during the year. The base of the tinplate scale was advanced from \$3.40 to \$3.60 a box precluding any increase under the sliding arrangement, and the general scale was cut about 5 per cent. besides. In sheets the base was raised from 2.30 to 2.50c., and

the general scale was reduced about 2 per cent.

The American company held a conference with representatives of the Tin Workers' International Protective Association and renewed the tin house scale for another year.

At a second conference with the Western Bar Iron Association held in Detroit on July 7 a settlement of the iron scale was reached. The new scale provided for reductions of 8 per cent. in the puddling branch and from 5 to 11 per cent. in the finishing departments. The Republic Iron and Steel Company accepted this scale later in the month when it was ready to start its idle union mills.

The Seaboard Iron Markets

The course of the trade on the seaboard and in Eastern territory is determined chiefly in New York and Philadelphia. New York is the distributing point for the State and New England, but Philadelphia is nearer the primary markets, and is directly connected with a large producing section in eastern Pennsylvania. The seaboard markets for the year followed the general course of the trade rather closely, and the variations were rather less than is usual in a year of depression.

The pig-iron market, which was practically the only open one, showed the greatest variations, as a consequence. For the greater part of the year foundrymen in Eastern territory bought on the hand-to-mouth plan, taking from time to time only such small lots as served their immediate needs. For these orders there was sharp competition among such furnaces as were kept in blast. It was a time when it was almost impossible to follow prices; cuts of 25 and 50c. were made from the nominal quotations, and these were kept quiet as far as possible. For several months there was considerable accumulation of unsold pig iron, and a natural disposition to try and work this off at almost any price was observed. About September a gradual stiffening began. The cast-iron pipe makers were taking a good deal of iron, and other foundries were increasing their requirements. Moreover, there was some rather active inquiry for basic pig, indicating some revival of business among Eastern steel makers. In October this business quieted down and the markets were dull until near the middle of November. Another revival set in, and by the beginning of December unsold iron accumulations were pretty well worked off. It was noticeable, however, that consumers continued the policy of buying for short deliveries only, and there was much reluctance about placing contracts for 1909. Very little business was done beyond the first quarter.

Through all the period of dullness Southern iron had the call in seaboard territory. Sales were larger, and the Southern furnaces kept in more active

operation than the Northern stacks during the entire year. At the close of the year the market shows more activity and greater firmness, the prices of \$13@13.50 Birmingham for Southern No. 2 foundry, and about \$17 seaboard for Northern No. 2 being fairly well established.

In finished material—with the exception of structural steel—the markets were dull throughout the year. Early in the year there was an expectation of lower prices, but these did not come, except in a very limited degree, and there was little change in the volume of business. As with pig iron, buyers took only what they required from time to time, and would not contract far ahead, except upon terms which sellers were unable to grant under the close restriction and supervision from which the markets suffered. Some revival set in in November, and there was some placing of contracts for the first quarter of 1909, but little beyond that time. There was also at this time an increase in demand for nails and other supplies used in small building, indicating a more hopeful condition as to that class of construction.

The structural market in the East showed some exceptions to the general rules. Owing to the withdrawal of money from the speculative markets, there was a large supply ready to invest in building projects, if conditions as to price should prove to be favorable. It was well understood that the Steel Corporation dominated the price situation, and its action was closely watched. The small and grudging reductions in structural prices made in June were a sharp disappointment. They were not enough to stimulate trade, but sufficient to induce hopes of further reductions. The immediate effect was to reduce the business that was ready to be offered.

A little later, however, structural trade began to revive, and more orders were placed. As the year went on the conditions improved, though nominally no further reductions in prices were made. The structural business in the larger cities of the East is done mainly with the large fabricating companies, which contract for the whole iron work of a building. Orders to the mills are sent by those companies. They began gradually to take orders and contracts for finished buildings at prices which, when closely analyzed, indicated a lower price for the steel than the nominal quotations. Though no acknowledgement of such reductions was made, there is no doubt that structural steel was supplied by many mills at cut prices. The exact extent of these cuts has been a secret guarded with unusual care, and it is impossible to give facts or figures. At any rate business improved, and during the later months of the year building and bridge contracts of large aggregate quantity were placed.

One feature of the year in the East was that there were not many failures or collapses in the trade, considering the gen-

eral depression of the year. Labor conditions were fairly satisfactory. The close of the year was quiet and opinions as to the outlook for the new year differ widely.

Mine Accidents and the Geological Survey

Under the terms of its appropriation of \$150,000 for the investigation of mine disasters, the Geological Survey has determined to establish rescue stations at or near the centers of mine accidents for the purpose of teaching miners how to use the most approved apparatus for mine rescue work. Government engineers will be assigned to the stations ready to go to the scene of any disaster, equipped with oxygen helmets. The stations will be supplied with air-tight rooms where gas can be generated, and coal-mining companies will be invited to send selected men to the stations for a sojourn. The men will then be trained in the use of the oxygen helmets. The Government does not plan to carry on general rescue work, but rather to assist mine owners in developing trained rescue crews at the mine, the rescue stations being erected in cooperation with the mine owners and State geological surveys.

The location of stations so far as determined on is as follows: At Urbana, Ill., in connection with the University of Illinois, for a district including, Illinois, Indiana, Michigan, Iowa, northern Missouri and western Kentucky; at Raton, New Mexico, for a district including New Mexico, Colorado, Wyoming, and Montana, with a second station possibly at Salt Lake City, Utah; at or near South McAlester, Oklahoma, for a district including Oklahoma, Arkansas, and southwestern Missouri; at an undetermined point (perhaps Knoxville, Tenn., Birmingham, Ala., or Lexington, Ky.) for a district including Alabama, Tennessee, Virginia, eastern Kentucky, Georgia, and southern West Virginia. George S. Rice, mining engineer, will be given general charge of the mining inquiries at these stations and J. W. Paul, formerly State mine inspector of West Virginia will be assigned supervision of all the rest of the work.

A second function of the stations will be that of acting as headquarters for the engineers engaged in the study of the waste of coal in mining. Safety lamps of all designs will also be tested at these stations in order to ascertain their general safety and efficiency.

Officers of the Survey express the opinion that much progress in averting the evil results of mine disasters can be made through the use of the oxygen helmets which have recently been demonstrated in one or two important accidents with what are considered good results.

Garnet in New York

By D. H. NEWLAND*

The abrasive garnet trade afforded no exception to the general course of business conditions during 1908. The Adirondack mines supplied, as heretofore, the greater part of the production of garnet for abrasive uses, but owing to the poor demand their output was reduced to less than one-half the total of the preceding year. The actual amount, as near as it can be estimated at this time, was about 2,000 short tons, compared with 5709 short tons in 1907. There was no corresponding decline in the prices obtained for the garnet, since the margin over the cost of mining is not large enough to admit any material reduction. Most of the output, also, was sold on contracts covering the annual requirements of the consumer.

No new companies have engaged in mining in the Adirondacks during the year. The North River Garnet Company, with mines and a mill on Thirteenth lake, has been the main producer. Since October, 1907, this company has been working a single shift only and suspended operations entirely for a period of three months last spring. On Gore mountain the mines of H. H. Barton & Son were run on a reduced scale. The Crechore mine near North River was inoperative throughout the year. A small output of massive garnet was reported from the new locality near Keeseville in the northern part of Essex county. This grade of garnet is mostly sold abroad.

A recent feature of the trade has been the introduction of foreign garnet which is finding a limited market in this country. It comes from Spain where it is said to occur in river sands, doubtless a product of the disintegration of crystalline rocks. The material can not displace the domestic product to any great extent as it is useful only for the finer sizes of abrasive papers. Garnet is a common ingredient of the sands found along the streams and lakes of the Adirondacks, but it seldom if ever forms deposits of any extent and is also always in finely comminuted condition.

The Cobar district in New South Wales is one of the most important sources of copper in Australia. The ore on smelting yields about 2.7 per cent. copper and 2.5 dwt. gold per ton.

The Luipaards Vlei mill (*South African Min. Journ.*, Sept. 12, 1908) crushed in August, 1908, an average of 9,677 tons per stamp per day. This is the record on the Rand.

*Assistant State Geologist, Albany, New York.

Note—These quotations were for ordinary wholesale lots in New York unless otherwise specified, and were generally subject to the usual trade discounts. In the cases of some of the important minerals, such as phosphate rock, pyrites and sulphur, in which there are well established markets, the quotations fully represent the latter. But in the cases of some of the minor mineral products, the quotations represent what dealers asked of consumers and not what producers realized in selling their outputs as matters of private contract.

Coal Mining in the United States in 1908

Reviews of Mining Conditions in Many Important Centers of Anthracite and Bituminous Production, with Forecasts of Future Production

TOTAL PRODUCTION, 418,968,000 TONS

The production of coal in 1908 showed less of a falling off when compared with the record totals of 1907, than was generally anticipated by those who were familiar with the apparent slackness in the industry during the year. The total output of coke, however, was rather less than expected.

From the best figures available at this early date, it appears that the coke production in 1908 was about 61 per cent. of the total output for the preceding year. The total coal production in 1908 was approximately 88 per cent. of the 1907 output.

The anthracite production showed a falling off of about 7 per cent., while the bituminous output was 14 per cent. less than in 1907. It is possible that a considerable quantity of the anthracite mined in the late months of 1908, has been stored as a provision in case of trouble on the expiration of the miners' agreement this coming spring.

The Coal and Coke Industries in 1908

BY FLOYD W. PARSONS

The close of 1908 shows a slow, but perceptible improvement in all branches of the coal and coke industries. The Eastern operators were more severely affected by the slackness in business than the owners of coal mines in the South and West. Likewise, the coke industry felt the depression in business considerably more than did the production of coal. The production of coke in the Connells-ville region, which district produces more than half of the total output of our country, showed a decrease in production of more than 10,000,000 tons, or about 50 per cent. of the 1907 output.

The enormous falling off in the production of coke was the natural result of the dullness in the iron and steel industries. Practically none of the coke operations in Pennsylvania and West Virginia has resumed on full time, although the outlook is more encouraging as the year draws to a close. In the Western States, the demand for coke was about equal to the output, during the latter half of the year. Both Alabama and Tennessee showed a slight falling off in coke manufacture during 1908; West Virginia produced about 70 per cent. as much coke

in 1908 as was produced in the preceding year.

In the production of coal, some of the smaller States made a much better comparative showing than the more important fields. Michigan, New Mexico, Oklahoma, Washington and Utah had an output in 1908 equal, and in some cases exceeding the production of 1907. As was true in the coke industry, Pennsylvania also showed the greatest percentage decrease in coal production during the year. West Virginia suffered a greater falling off in production than did Illinois, so that the latter State will easily retain its place as the second largest producer in the Union. The production for that district formerly known as Indian Territory is now included under Oklahoma.

CAR SUPPLY AND LABOR CONDITIONS

During the two years preceding 1908, the operators were much distressed over the lack of cars and the scarcity of labor. It is safe to say that no district suffered to any considerable extent from these causes during the past 12 months. There were no important labor troubles, excepting the Alabama strike, and but few wage reductions. The cause of organized labor made practically no headway in bringing new districts into the fold of the Union.

The year brought forth much discussion concerning the advisability of providing our miners with a higher education, so that a better understanding of the elementary problems attending coal mining, might result in bringing about a decrease in the number of mine accidents. These efforts to advance labor to a higher plane of intelligence have been undertaken along two lines: 1. Several of the larger companies have established night schools which provide instruction for all miners, free of charge. The expense incurred in carrying on this work is borne entirely by the mining company. 2. A general belief has arisen that all miners should be compelled to serve an apprenticeship before they are permitted to undertake important or responsible work. Along this same line, pressure is being exerted in several States with the idea of raising the standard of eligibility for mine foremen and fire-bosses.

Several important coal companies were organized during the year, but little new development was undertaken. It was expected that during 1908, the Hepburn law would become effective, and that

as a result of the enforcement of this new legislation, many of the larger anthracite and bituminous companies would be obliged to reorganize and operate independently of the controlling railroad company. The test case against the anthracite coal companies was decided early in the year in favor of the railroads; the case was appealed to the Supreme Court and will probably be decided in 1909.

MINE ACCIDENTS

The question of coal-mine accidents, their cause and prevention, has been the all important subject of discussion during the past 12 months. The year has brought forth many new, if not startling ideas. In the expression of these opinions, our most prominent engineers have differed widely in their views. Several mine managers have made the assertion that we are sending too much air through our mine workings, and that before we adopted such elaborate systems of ventilation, explosions, especially those due to coal dust, were not so frequent. It has also been stated that the practice of sprinkling our mines in order to settle the dust and prevent dust explosions is in error; the opposition to this plan of introducing moisture into our mines, bases its opinion on the idea that excessive moisture in mine air causes roof falls, and thereby adds largely to our list of fatalities.

It is safe to say that the majority of mine managers do not agree with the foregoing statement, and that the introduction of a reasonable amount of moisture into mine air, as well as the practice of sprinkling the dust at the face of rooms and entries before shots are fired, is a precaution that insures greater safety to the miner working underground.

There is no question but that the great number of roof falls is a serious menace to the safe operation of coal mines; however, it is doubtful if we can safely reduce the volume of air at present being sent into our mines or increase the factor of safety by neglecting to sprinkle dusty working places. It is probable that in the future when such problems are better understood we will find that underground, as on the surface, rock disintegrates not so much from either dampness or from an atmosphere of unusual dryness, but rather from the frequent change to one or the other of these extreme conditions.

If we could keep the moisture in our mine air at a certain standard all the year round, we would then materially reduce the number of roof falls due to the disintegration of the top rock.

COAL DUST EXPLOSIONS

The problem of eliminating coal dust as a factor in mine explosions has been the principal subject occupying the attention of coal engineers during the year. The first precaution to adopt is to remove as much of the dust as is practically possible. After this has been accomplished, there still remains an immense quantity of finely divided dust that must be taken care of. This powdered coal will not explode so readily or lend itself to a gas explosion so quickly when it is in a dampened state. Therefore, it seems that so far as present knowledge teaches, the only proper thing to do is to bring this dust to a condition of dampness, thus rendering it less dangerous in case of an explosion. Experiments by English engineers have shown that when rock dust is mixed with coal dust, the latter is rendered in-explosive. Whether this theory can be brought to a point where it will be a practical benefit, remains to be determined.

There are many other modern practices that are looked upon with disfavor by a few. Several important operators have recently declared themselves as opposed to mining machines, and they have stated openly that in solving our difficulties we must again return to pick mining. It is probable, however, that all of our advanced ideas that have been put to practical use have come to stay, and that those who claim to believe that our increased losses of life are due to high ventilating currents, sprinkling our mines, using mining machines, etc., have overlooked the fact that we now operate on a scale of magnitude with which former systems appear primitive. Our large mines are now many times the size of the important producers of a few years ago, and if anyone doubts that our advancement toward better methods has been slow, it is only necessary for him to investigate the working plan of any mine in any district as operated a decade ago, and then compare this map with the modern mine plans that exist in that same district today.

Comparing the present with the past in coal mining, there is not the slightest doubt but that this industry has advanced with equal, if not greater rapidity than other similar enterprises.

BLOWN-OUT SHOTS

The important coal-mining problem to be solved during the next year is that of shot-firing. An examination of the causes assigned for the various coal-mine explosions during the past decade has shown that in bituminous

mines, which latter furnish us with the majority of our serious disasters, the great majority of explosions are due to blown-out shots. Although it is the practice of almost every coroner's jury to bring in a verdict, stating that the accident was due to a blown-out shot, which, of course, means that the miner was negligent and that the company is not to blame, it is nevertheless true that about 90 per cent. of our explosions, where dust has been a factor, are directly caused by such faulty shots.

The various powder manufacturers, and the Federal Government at its experiment station in Pittsburgh, are rendering great service in providing us with a better knowledge of the correct kind of powder to use. There is one practice that must eventually be adopted at every coal mine, and that is to have all the shots fired by a special corps of shot-firers. Furthermore, all holes should be fired when the miners, with the exception of the shot-firers themselves, are out of the mine at the end of the day's work. There are no less than 100 important mines in our country today where the continual shooting in the various rooms makes the mine air so cloudy from smoke, dust and gas, that the mine surveyors, with their transits, cannot see a sufficient distance along the entries and up the chambers to enable them to put in their sights properly. Promiscuous shooting of this sort is dangerous and is sure to result in disaster.

When it is suggested to operators that they should have all shots fired by regularly appointed men who do this work after the miners have left the workings, the immediate reply is that the plan is impracticable because of the expense attached, and that there would surely be a falling off in production. Our mines are not institutions owned and operated by wealthy men for the cause of charity, and consequently it is useless to suggest that they adopt beautifully devised schemes that will make their mines safe, and at the same time cause them to show a financial loss at the end of the year. Competition in coal mining is as keen as it is in any other business, and legislators, theorists and students of reform, must remember that it is more desirable to close down a plant than to adopt measures which are sure to result in a loss. It is the common practice of reformers to devote their principal attention to reforming the other fellow's business methods instead of looking to the improvement of their own.

There are mines in this country, as well as in several European fields, where shot-firing, as before recommended, is carried on successfully, both from the point of safety and economy. I do not believe that conditions in any field in our country are such as to prohibit shot-firing by specially appointed men after the day's work has

been done. It has been suggested that this practice is dangerous, especially if the miners charge their own holes, for when they do not fire the shots themselves, they are not so careful about loading and tamping the holes. This point is undoubtedly true to a small extent and cannot be entirely eliminated so long as we have to deal with the personal factor. It is better, however, if we must have explosions, that 8 or 10 men lose their lives than 10 or 20 times that number.

MINE RULES MUST BE ENFORCED

We have examples each day where miners deliberately disobey all rules, and for the sake of personal gain, endanger not only their own, but the lives of fellow workmen. This can only be avoided by stricter supervision, and if necessary, by having a number of additional police underground. The Marianna mine, for instance, which was designed to be a model operation, was as dangerous as any poorly planned and badly managed property could be. The sole reason for this was due to the violation of rules by certain miners who carried black powder into the workings, and even went so far as to use cartridges filled with coal dust for tamping.

We must hold all miners responsible and see that they are severely punished for any infraction of prevailing rules. On the other hand, mine operators should be held responsible if they do not take every possible step to properly police their mines, and thus prevent such reckless violations. Coroner's inquests are laughable comedies, where no one but the dead are held responsible, and where the defendants suggest the questions put to themselves. No matter how many virtues we possess, we are sure to be more careful when we know that there is a possibility of responsibility and blame being laid at our door. In fairness to the honor we all claim to possess, and to those unfortunate who pay the heavy price, we must be willing to assume the burden of blame when it is ours.

The Chicago Coal Market in 1908

By E. MORRISON

From the point of view of the dealer in steam coals, particularly those from the Illinois and Indiana fields, the year 1908 has been disappointing. The demand for such coals has been low throughout the year and although demand steadily bettered in the last three months of the year, it averaged probably 20 per cent. lower than in 1907. Prices of Western bituminous were low, but continued without any material reduction from the previous year, when keen competition brought them down to a low level. Domestic coals were low-priced and the lack of universal pros-

perity aided the western producers somewhat by bringing into demand low-priced bituminous as a substitute for anthracite and high-priced eastern bituminous.

The year opened with a weak market owing to mild weather and business depression. By February the demand for both bituminous and anthracite improved greatly and demurrage evils practically disappeared. In the first half of March, the demand became light again, although in the latter half the buying was heavy because of apprehension that a strike was impending in the bituminous-producing regions; the month of April, in which mining was generally suspended throughout the western fields, saw little demand for coal and no rise in prices. Consumers and retailers alike refused to lay in large stocks.

In May, after the arrival of new supplies from the fields where mining had been suspended, the trade quieted down to a steady and dull condition that lasted with hardly a break until November, when a condition of slow improvement began. Fine coals were more generally in demand throughout the summer than in any previous year. Contract making was not so large or so general as in the previous year, open market conditions being too favorable to the consumer.

For harvesting purposes, the demand in summer and autumn was large and this helped to hold up the level of prices. Fine coals began to weaken in September and dropped to a condition of enforced sales at low prices, to escape demurrage, by October. Lump strengthened gradually as the autumn months brought an increased demand for domestic supplies, but the slow market for lump continued without noticeable strength up to the end of the year, owing to lack of cold weather and the slowness of the revival of general business.

The range of average car prices of Illinois and Indiana coals, which formed about two-thirds of the total supply received in the Chicago market, was as follows:

PRICES OF WESTERN COALS (CHICAGO).

Mo.	Lump and Egg.	Run-of-Mine.	Screenings.
Jan..	\$1.00@\$.25	\$1.60@\$.10	\$1.20@\$.10
Feb..	\$1.90@\$.25	\$1.60@\$.10	\$1.20@\$.10
March	\$1.80@\$.25	\$1.60@\$.10	\$1.20@\$.10
April	\$1.75@\$.25	\$1.60@\$.10	\$1.20@\$.10
May..	\$1.75@\$.25	\$1.60@\$.10	\$1.20@\$.10
June..	\$1.75@\$.25	\$1.60@\$.10	\$1.20@\$.10
July..	\$1.75@\$.25	\$1.60@\$.10	\$1.20@\$.10
Aug..	\$1.75@\$.25	\$1.60@\$.10	\$1.20@\$.10
Sept.	\$1.75@\$.25	\$1.60@\$.10	\$1.20@\$.10
Oct..	\$1.75@\$.25	\$1.60@\$.10	\$1.20@\$.10
Nov..	\$1.75@\$.25	\$1.60@\$.10	\$1.20@\$.10
Dec..	\$1.75@\$.25	\$1.60@\$.10	\$1.20@\$.10

The demand for anthracite was quiet throughout the year, car prices being the same as in the previous year—\$6.50 for egg, stove and chestnut, and \$6.25 for grate. As for several years previous, the graduated monthly discount system was in

use between April 1 and Sept. 1, giving 50c. off on April sales, 40c. on May sales and thus down to 10c. off on August sales. Retailers and consumers bought lightly in the closing months of the year, mild weather chiefly accounting for their apathy.

Eastern bituminous coals suffered throughout the year from a tendency of steam users to seek low-priced coals, and throughout the summer and autumn from over-supply. High-grade smokeless coals sold fairly well as a result of persistent advertising; low-grade smokeless was moved with difficulty and was constantly sold at less than circular prices. Smokeless brought \$3.95@3.30 for run-of-mine, and \$3.85@4.05 for lump. Hocking shipments were well restricted and though the demand was not heavy it was fairly uniform, the price ranging \$2.95@3.15. Youngiopheny was very quiet and steady throughout the year at \$3.15@3.25 for 34 inch gas.

Many producers of bituminous coals learned greater caution about sending surplus products to the Chicago market, in 1908. The desirability of regulating the supply so as to prevent flood waves of shipments of one kind of coal or another has often been pointed out and was emphasized by the year's history. In default of such regulation, shippers found most uniform success in closely watching the market rather than in taking speculative chances.

Pittsburg District Coal in 1908

By S. F. LUTY

Coal production in the Pittsburg district in 1908 did not come up to the prediction made late in the previous year by fully 20 per cent. With data for December and from some independent companies unavailable, it is estimated that the production in the Pittsburg district and including the Westmoreland field did not exceed 42,000,000 tons, a decline of about 10,000,000 tons compared with 1907, a record year, and equal to the output of 1905.

The Pittsburg Coal Company, the leading interest, in the first nine months produced 9,726,387 tons compared with 13,302,634 tons in a like period of the previous year. Its total for 1908 was nearly 13,000,000 tons as against a trifle over 15,000,000 tons in 1907.

The Monongahela River Consolidated Coal and Coke Company produced in round numbers 6,000,000 tons, or 1,500,000 tons less than the previous year and equal to the production of 1906. Of this tonnage 2,250,000 tons went to lower river ports, and 1,500,000 tons was shipped by rail. The rest of the tonnage was distributed among the manufacturing interests along the Monongahela, Allegheny and

Ohio rivers and in the home market. Other river-coal interests produced about 2,250,000 tons, or about 750,000 tons less than the previous year.

River shipments were very good for the first five months of the year, but the rivers have not been navigable since the second day of June. What coal was not consumed in the home market, or shipped by rail, was still in the pools and harbor at the close of the year, and amounted to a round tonnage of 700,000 tons, or about 20,000,000 bu. When navigation was suspended in June there were enough empty coal boats and barges in the pools to keep the mines running for two months. Since that time operations were practically suspended, only rail shipments being made. About the middle of December the rains brought the rivers to a stage that permitted the return of empties and a partial resumption of the river-coal mines followed.

LAKE TRADE WAS DISAPPOINTING

The lake-coal trade also was disappointing. In 1907 the Pittsburg Coal Company and other interests shipped 10,485,000 tons to the northwestern market, and in 1908 shipments fell off to around 8,000,000 tons. One reason was the late opening of lake transportation. In former years ore was sent down the lakes as soon as navigation was opened, but owing to conditions in the iron and steel trade no ore was shipped until June 1, and as coal is shipped on the return trip of these boats, none went out before the middle of June. Shipments to lake ports began at the usual time, but the docks at Cleveland soon became congested, and there was considerable delay.

Prices remained throughout the year on the basis of \$1.15 for mine-run coal at the mine for both river and rail shipments. Producers figured that as the demand was not normal no advantage would be gained by cutting prices as it would not bring any more business. Some of the small producers, however, did shade the price, but not sufficiently to disturb conditions. Slack fluctuated, the highest point being 80c. and the lowest 40c. a ton at the mine.

A general suspension occurred on April 1 owing to the expiration of the two-year wage agreement on the mining rate with the United Mine Workers of America. The interstate agreement was dissolved when the joint convention, held at Indianapolis in January, failed to reach a settlement. The mine workers' organization demanded a renewal of the wage scale, which was on the basis of 90c. per ton for pick mining over a 14-in. screen. The two-year agreement expired on March 31, and the miners wanted an agreement for a period of one year. At a conference held in Toledo in April, a settlement was reached and a contract for two years was made.

NO SCARCITY OF RAILROAD CARS

For the first time in many years there was no complaint of a scarcity of railroad cars. Idle cars could be seen at the mines at almost any time, and there was no delay in shipments. It is not likely that any of the annual reports of the different corporations will show serious losses, but all profits were greatly diminished and dividends were not paid by some large concerns.

At the annual meeting of the Pittsburg Coal Company, held in Jersey City in February, all officers were reelected. The report showed that the gross earnings of the company for the year 1907 increased \$434,859.95, or 8.21 per cent. Net earnings for 1907 showed an increase of \$765,824.88, or 34.93 per cent.

The only serious accident of the year was the explosion at the Marianna mine of the Pittsburg-Buffalo Company on Nov. 28, when 154 lives were lost. It was caused by a blown-out shot which ignited gas and dust.

Following is the verdict of the coroner's jury at the inquest on the body of one of the victims:

"We, your jury, after hearing evidence of mining experts, inspectors, miners and operators, find that John J. Ivill came to his death from an explosion in the Marianna mine, West Bethlehem township, Washington county, Penn., Saturday, Nov. 28, 1908, and that said explosion was due to a blown-out shot in Blanche entry No. 3, which ignited the gas and dust, and that a secondary explosion occurred in the main dip entries almost simultaneously.

"We further find that no blame is attachable for said accident and we recommend that mine inspectors frame and submit to the incoming legislature a set of rules to be adopted into laws, namely:

"For the employment of experienced shot-firers to fire all shots; that all shooting be done between shifts, and that black powder and other highly inflammable explosives be excluded and the excessive use of brattice cloth be prohibited. That all charges of explosives be stemmed with clay; that safety lamps be used exclusively in gaseous mines; that an efficient water system be installed and the dust in all parts of mines be fairly wet.

"And further, owing to the fact that laws governing electricity in mines are very meager, that a more rigid set of laws be submitted for adoption."

CONNELLSVILLE COKE IN 1908

Coke production in the upper and lower Conneltsville fields in 1908 was fully 5,000,000 tons less than the previous year. The output of the H. C. Frick Coke Company with December estimated was in round numbers 7,000,000 tons, and the independent interests produced about 6,000,000 tons. At times during the year less than 50 per cent. of the ovens were in blast.

A number of ovens were closed late in the previous year when the depression in the iron and steel trade began. In January conditions became worse, and thousands of men were thrown idle. Most of them were foreigners, who returned to their former homes where they remain awaiting a return of better times.

At the opening of the year furnace coke had dropped to \$2 and foundry coke to \$2.50. These prices did not continue long until there was a further decline, and sales of furnace coke during the year were made at from \$1.60 to \$1.75, and foundry at from \$1.90 to \$2 per ton. On account of the low prices, the H. C. Frick Coke Company made a reduction in wages effective Jan. 1. No change was made in some classes of labor, and the reductions in others ranged from 5 to 12 per cent. A readjustment was not a surprise, as coke prices had declined fully \$1 a ton compared with the prices in the first quarter of 1907. On March 1 of that year the Frick company voluntarily advanced the wages of its workers from 8 to 12 per cent.

At the close of the year furnace coke for spot shipment was quoted at \$1.85 and on contract at \$2. Foundry coke late in December was quoted at from \$2.25 to \$2.40 for both spot shipment and on contract.

Alabama Coal Production for 1908

BY L. W. FRIEDMAN

Statistics from the coal-mining industry in Alabama are always slow in being received at the office of the State Mine Inspector, J. M. Gray, and consequently the estimates are necessarily based on the figures submitted for the early months of the year. The production of coal in Alabama in 1908 will show a falling off of at least 2,000,000 tons in the aggregate as compared with the output of 1907, the estimate being that the production for the past year will total about 11,900,000 tons. The production in 1907 was 14,248,863 tons against 12,851,775 tons in 1906.

During the year 1908, in addition to the depressed conditions throughout the country, there was a big strike on in this State: the United Mine Workers of America carried on the struggle from July to September. The State was asked for troops and the militia was called out for more than a month. The sheriffs of Jefferson, Walker, Bibb and Shelby counties, in Alabama, were called on for protection and the necessity of deputies was shown and responded to. The laborers brought in to replace the union men had much trouble in remaining at work, and the production of coal, except at mines

where convict labor was employed remained unsteady and unprofitable.

Summary of Coal Industry in Colorado During 1908

BY JOHN D. JONES*

The coal production of Colorado in 1908 was 9,773,683 tons; this was 1,191,957 tons less than the tonnage of 1907. The relapse in production is accounted for by the tightness of the money markets prevailing during the earlier part of the year, and which resulted in shutting down many fuel-requiring industries in adjoining States, and canceling the orders contracted in this State to supply the coal. The plants of many metalliferous mines in Colorado closed, or limited their producing forces, which in turn curtailed the freight traffic and considerably slackened the demand of the railroads for fuel.

In addition, the winters of 1907 and 1908 were exceptionally mild, and this, together with the above stated reasons, seriously affected the trade. In consequence numerous coal mines were obliged to suspend operations, and some did not resume business until late in the fall. There were but few mines working to their full capacities. At the present time nearly all the mines which ceased operations pending better markets have reopened and are forging ahead with renewed activity. The depression in the trade did not affect the wages of the miners, nor the price of coal.

The relation between operators and employees in general has been harmonious, and no labor troubles occurred to interfere in any noticeable way with the total production of coal.

The supply of railroad cars has been unusually regular, although at times there have been shortages, caused more through the inability of the companies to furnish motive power to haul the coal than to a lack of cars.

ATTENTION WAS DIRECTED TO MAKING THE MINES SAFER

What makes the year a memorable one is the fact that in spite of the poor demand for the commodity the operators turned their efforts in another direction. The low financial profits of the year did not discourage them, and they took this opportunity to place their mines on a safer and better working basis, both for the protection of the employees and the safeguarding of their property: it was also true that in many instances attention was directed toward developing larger producing capacities. In short, a general desire was manifested to place the mines on a safer and more sanitary basis, with the view of meeting increased demands of trade. A number of new mines were opened which are not yet producing, and

*Chief coal mine inspector, Denver, Colo.

which will, when completed, be equipped with modern and costly appliances.

From the fact that many of the industries which were shut down a year ago, have resumed operations and new ones have started up, there is every indication that the coal industry of this State is on the verge of a prosperous era, which will result in a material increase of tonnage in the years to come.

The following summary in which the December totals were estimated gives a fairly accurate digest of the industry during the past year:

SUMMARY OF THE COAL PRODUCTION OF COLORADO FOR 1908.

Number of producing mines.....	190
Number of new mines opened.....	18
Tons of lignite coal produced.....	1,991,234
Tons of semi-bituminous coal produced.....	818,272
Tons of bituminous coal produced.....	6,824,737
Tons of anthracite coal produced.....	69,440
Tons of unclassified coal produced, estimated.....	70,000
Total tonnage produced.....	9,773,683
Total tonnage of coke manufactured.....	894,662
Total number of coke ovens.....	2,811
Number of employees at the coke ovens.....	1,104
Number of employees in and about the mines.....	14,126

The Illinois Coal Industry in 1908

SPECIAL CORRESPONDENCE

The production of coal in Illinois during 1908 showed but little change when compared with the output of the preceding year. Labor troubles which occurred in the central fields early in the year, caused the closing down of many mines. The demand was so slack, however, that it is probable the output would have been no greater had there been no enforced suspension of work. The depression in business caused many consumers to use the cheaper grades of bituminous coals in preference to the more expensive anthracite product.

According to the reports of the State mine inspector for the year ending June 30, 1908, there were 54 counties in Illinois producing coal. The number of mines and openings of all kinds that were being operated totaled 922, while 97 of these operations were new developments of the year. There were 108 mines closed down during the year which shows that the abandoned operations exceeded the new developments by 11. The latter half of 1907 which is included in the fiscal year ending June 30, 1908 was the period of greatest production. The total output for the year ending June 30, 1908 was 49,272,452 tons. Of this production, 47,809,730 tons were produced by 407 mines, while the remaining 1,462,723 tons were produced by 515 mines which latter were engaged in local trade only. The average value per ton for all grades of coal at the shipping mines was \$1.02. The aggregate home value of the total product was \$50,989,082. There were 105 mines in which machines were used, which com-

pared with 101 machine mines in the preceding year. Of the total production, 15,210,423 tons were produced by mining machines. The total number of employees is estimated at 70,841, of which number, 64,424 work underground.

The average price paid per gross ton for hand-mining was 59.3c.; the average price paid per gross ton for machine mining was 46.7c. In blasting the coal the miners used 1,328,454 kegs of powder. In operating the mines throughout the year, the number of men killed by accidents totaled 175. These fatalities made 89 widows and left 217 fatherless children. For each life lost, 281,557 tons were mined. There were 2.5 deaths per 1000 employed; it is also estimated that there were 3.6 men killed for each million tons produced.

Indiana Coal Production in 1908

SPECIAL CORRESPONDENCE

Indiana continues to hold a place in the ranks of the six principal coal producing States; however, conditions of mining and coal trade during the past eleven months were not equal to the corresponding period of 1907. The total coal production in Indiana in 1907 was 13,985,713 tons, having a spot value of \$15,114,300; this output was an increase of 1,893,153 tons over that of 1906. While the growth of the industry has been remarkable it is estimated that the production for 1908 will only be about 12,000,000 tons, or a decrease of nearly 2,000,000 tons as compared with 1907.

There are several important factors, which, in addition to the general financial and industrial depression during the present year, played an important part in the large decrease in the output. After the month of March, two months were required to adjust satisfactory working conditions, wages, etc., with the mine workers; the drought had some influence; there were a few strikes and labor troubles, but the principal, controlling feature was the lack of orders. Heretofore, Indiana has furnished a large amount of steam coal to manufacturers throughout the central States. This demand was curtailed nearly one-half. The Ohio river market, because of the low stage of water, was cut out, and this loss was perceptibly felt by the producers of southern Indiana. The usual demand for domestic coal from the Northwest was tardy and not up to volume, while the lake demand was by no means equal to previous seasons.

Considering all these conditions which contributed to the closing of a number of mines, the decrease in the estimated output is not greater than the decrease or depression in other business enterprises.

About 21,000 miners have been employed in the Indiana mines during the year. The average number of days worked were less than the previous year. The operators in many instances took occasion to improve their mines during the slack time and employed the idle miners to do the work. In addition to putting the plants in good condition, several new mines were opened and a number of old and abandoned operations were repaired and worked in a limited way.

IRON ORE IS TO BE MINED

A start has been made in the iron ore mining and smelting business in this State. A smelter has been established and equipped at Linton, and ore is being mined in the Greene county field and shipped to Linton where crucial tests are being made relative to the quality and richness of the ore. It is understood that the Steel Corporation at Gary is back of the test. It is generally known that this latter company holds an option on a large acreage of the iron-ore land.

Coal has been found in several localities in the State heretofore unknown to contain workable seams. In each case the work of developing the new field is being pushed successfully.

The special session of the legislature amended the prevailing laws so as to make the use of a 3/4-in. bit permissible, instead of the 2 1/4-in. bit prescribed by the law of 1907. The operators are not inclined to furnish the larger bit because of the increased danger, and this has precipitated serious trouble in the Clinton district.

There have been fewer accidents and explosions in the mines than last year and the fatalities from this source will not exceed six or eight lives.

Notwithstanding the decreased output, there is a decidedly optimistic feeling among the operators, who share in the belief that the future will restore the industry to its accustomed activity, and doubtless, during the next two years, the yearly production will surpass any previous totals.

Coal Mining in Iowa in 1908

BY JAMES H. LEES*

The coal-mining industry in Iowa has not been quite so active during the present year as it was in 1907. This has manifested itself in a reduction in the number of days the miners worked, and a consequent diminution in the coal output. This latter, however, has not amounted to a great deal as a comparison of figures will show. In 1907, according to data collected by the Iowa Geological Survey, the output amounted to 7,574,322 short tons. In 1908

*Assistant State geologist, Des Moines, Iowa.

the production was about 7,050,000 short tons, the figures being based on the closest possible estimates.

There was a number of causes contributing to this decrease. One of these was the falling off in railroad business, which was especially noticeable in the early part of the year, notwithstanding the increased passenger traffic due to the 2c. fare. Another cause was the suspension of mining operations during April, pending the adoption of the working agreement by the operators and the miners. Still another reason has been the mild weather prevailing during most of the fall months. Even in December many of the mines have worked only four or five days a week, and this is true of railroad mines as well as of others.

MUCH ACTIVITY IN NEW DEVELOPMENT WORK

Perhaps one of the most important factors has been the shutting down of numerous worked-out mines and the delay in opening others, together with the gradually decreasing output of some of the old mines. This factor is partially offset by increasing activity in prospecting and exploitation in certain counties in the central coalfields, notably Boone and Dallas. Here there has been more prospecting and development than for years past. This is due to the finding of several good seams of coal at greater depths than had been prospected before, depths varying from 170 to 270 ft. One firm has recently secured control of some 7200 acres of coal land in these two counties. Polk county, in the same general field, has also received an impetus through the opening of about 10 new mines; the larger size and superior equipment of these mines will result in increased output in the near future.

Another element which will aid in advancing the production in 1909 will be the more settled market conditions throughout the country and the stability and confidence engendered by the Des Moines agreement between the miners and the operators which will be in force until March 31, 1910. This will both enable the operator to reach out after new markets and longer contracts, and will insure better mutual consideration from both parties.

ACCIDENTS

In spite of the slight decrease in production, there has been some increase both in the number of mines operated and of the employees. Over 330 mines were in operation, giving employment to 17,312 men. During the fiscal year ending June 30, 1908, there were 38 fatal accidents, or 2.2 per 1000 employees, in addition to 100 serious, nonfatal accidents. This means the loss of one life for each 188,301 tons mined, and serious injury to an employee for each 71,544 tons raised. It must be said that these accidents are in a considerable measure due to the carelessness of

the miners themselves, since the Iowa mining laws are broad, and are for the most part well lived up to by the operators. During the last half of 1908, fewer accidents have been reported than for some time previous.

The use of mining machines is not extensive in Iowa, and the same may be said of electric haulage, etc. Many mines are not large enough to use them profitably, and the broken nature of the deposits also tends to discourage the installation of expensive equipment except in the larger fields.

Taking all things into consideration in Iowa, the past year has yielded all that could be expected and the coming year holds out promise of improved conditions for the coal industry.

The Coal Industry in Michigan in 1908

There was much activity manifested in the operation of coal mines in Michigan during the year just passed. Thirty-five mines were operated, and the average number of employees was about 3200. The average daily earnings of each employee was \$3.05, and the aggregate sum paid in wages totaled to nearly \$1,200,000. The average cost of each ton of coal produced was approximately \$1.60. The most reliable estimates place the coal production for Michigan in 1908 at about 2,000,000 tons.

Coal Mining in New Mexico in 1908

SPECIAL CORRESPONDENCE

The coal-mining industry in New Mexico during 1908 did not prove as prosperous as anticipated, although the percentage of increase will fall but little short of the average of the past 10 years.

There was every reason to expect a much greater increase of production, as the larger mines had recently been equipped with machinery of the most improved design and of far greater capacity than had heretofore been used in the Territory; increased development work had been carried on for a year previous, in order to satisfy the great demand for coal, which, during the two previous years it was impossible to fully supply.

The demand for coke had also far exceeded the supply, and a considerable percentage of the coke for the metal-smelting plants of the Southwest and of Mexico, had been brought from Colorado, Pennsylvania, Australia and Germany.

To help in supplying this demand, 446 new underflue ovens were completed at Dawson, in the fall of 1907. Two hundred and ten new beehive ovens were

built at Koehler, and 110 new beehive ovens had been recently added to the coking plant at Gardiner, New Mexico.

The general business depression of the fall of 1907 was felt most acutely by the copper mining and smelting companies of the Southwest, because of the greatly lessened demand for their product. Through the channel of the copper-producing companies, the coal mines and coke plants were similarly affected. Therefore, instead of any large gain in production, the percentage of increase fell slightly below the average. The fact that miners were plentiful to operate the mines and that transportation facilities were better, to some extent compensated for the lessened demand; but the capacities of the mines for production were not taxed to near their limit, nor indeed given a test of what might be accomplished.

THE PRICE PER TON WAS LESS THAN IN 1907

From January 1, 1908 to July 1, 1908, fully one-half of the coke ovens in the Territory were idle, and the mines were operated on half time; in one or two instances some of the mines temporarily suspended operations. About July 1, an increased demand for coke aided the demand for the product of the coal mines. However, an unusually warm fall and winter throughout the Southwest and Pacific coast lessened the demand for coal until November 15, after which date the inquiry for coal has been increasing. The demand for coke is at present keeping all of the 966 ovens in the Territory constantly in operation.

During the year just closed there was produced from the mines of New Mexico 2,725,000 tons of coal, of which 75,000 tons were used in operating the mines and for domestic purposes at the camps; 310,350 tons of coke were produced, requiring 558,630 tons of coal, or 1.8 tons of coal for each ton of coke produced. Approximately 2,091,370 tons of coal were shipped, the average value of which was \$1.40 per ton, a fall in average price, by reason of the lessened demand and greater competition for orders, of about 45c. per ton from prices prevailing in 1907.

An average of 3200 men were employed underground in the mines, and 740 on top, or a total of 3940 men in the immediate operation of the mines; 120 boys were also employed, 72 of whom were underground and 48 on top.

Fully as many persons were employed on the outside in cutting and hauling timbers, operating coke ovens, electrical plants, saw mills and performing other duties incidental to the operation of the mines.

Twenty-one persons lost their lives in the coal mines of the Territory during the year; fourteen of these unfortunates were killed by falls of rock.

The percentage of fatalities is very high, 5.17 per cent., and it can only be remedied by more stringent laws against carelessness in timbering the mines, and by the enforcement of better discipline in the operation of the mines.

With a revival of business conditions throughout the country, coal mining in New Mexico will assume much greater proportions than heretofore, and will move forward with rapid strides.

West Virginia Coal Industry in 1908

SPECIAL CORRESPONDENCE

It is estimated that West Virginia produced 44,091,000 short tons of coal during the year 1908. The coke production was approximately 2,978,000 net tons. The number and seriousness of the accidents in West Virginia during the year showed a great falling off from the appalling figures of 1907. The year's record did not record any such disaster as the one that occurred at the Monongah mines in the 12 months preceding.

Every effort has been made by the State Department of Mines, as well as by the operators, to reduce the number of fatalities to a minimum. With the possible exception of Pennsylvania, it is probable that West Virginia felt the depression in the coal business, to a greater extent than any other State. There were no labor troubles of consequence, and the miners, as a rule, still remain in the ranks of unorganized labor.

Chief Mine Inspector Paul has severed his connection with the State to accept a position with the United States Geological Survey experimental station corps. John Laing, a mine superintendent of experience, has been appointed chief inspector to succeed Mr. Paul. At the close of the year, the outlook for the coal industry in West Virginia is much brighter, and it is expected that the output in 1909 will equal the record production of 1907.

The Coal Mining Industry of Washington in 1908

BY RAYMOND P. TARR*

During the past year more real advances have been made in coal-mining development in the State of Washington, than during any like period of its history. In the person of D. C. Botting, inspector of coal mines, the State possesses a painstaking, capable official who is popular with the laborer as well as the operator.

Both the Northwestern Improvement Company and the Pacific Coast Coal

Company have signed a two-year agreement with the officials of District No. 10, United Mine Workers of America. This agreement is effective Sept. 1, 1908. Previously, the agreement has been for a one-year term.

The coal output has been less than that of 1906, but slightly greater than the production of 1907. Since 1906 the Northwestern Improvement Company has not been engaged in the domestic trade, and has mined solely for the supply of the Northern Pacific Railway Company. Owing to the working out of areas within the fields of the Pacific Coast Coal Company, the output of this latter corporation has fallen short.

At Coal Creek, the Pacific Coast Coal Company has driven a slope to obtain a vast amount of coal in this district lying below water level. The first level, 500 ft. down, has been driven for 4000 ft. in both directions. The slope mouth is 14 ft. in the clear, and is concreted for 40 ft. This company has started a new slope at Burnett, which will tap a body of coal to the extent of several million tons. Black Diamond, Wilkeson and Carbonado, have all done well and are progressing under good management. None of these operations have much to chronicle in the way of construction, however. Carbonado leads in development work. Some trouble over the labor question has kept Wilkeson in a state of unrest during the year.

NEW DEVELOPMENT WORK

During 1908 the Roslyn Fuel Company has gotten well under way in the development of its holdings on the north end of the Roslyn field. Their slope is fine in every particular and is still going down; three right and left gangways have already been turned off. The entire equipment of this mine is decidedly up-to-date. The daily output is 400 tons, and this property is doing much to relieve the decidedly tight straits of the fuel market. The "Patrick and McKay" mine nearby, and the Summit Coal Company at the south end of the field are the other producers in this section.

The Mendota Coal and Coke Company has just completed building eight miles of railroad into the coalfield east of Centralia. The management here is proceeding slowly and everything that is being done is of a permanent and modern character. The Washington Union Coal Company has built a railroad into another portion of this field where the coal is decidedly more lignitic than that found in the former district.

The Northwestern Improvement Company has completed at Ravensdale its new cleaning plant with a 1500-ton daily output. Conditions after the flood and fire are again becoming normal, although the management has suffered two years of reverses at this mine. The company has invested much new machinery at Roslyn,

such as rotary car dumps, car hauls, box-car loaders, etc. No. 7 mine, at Clealum, and No. 3, at Roslyn, have been opened. Both these operations have been equipped with new tipples. The Roslyn daily output has passed the 700-ton mark, which establishes a new record for the State. Shot-firers are employed at most of the Roslyn mines, and the battery system has been instituted; the whole field is well regulated and is worked according to set standards.

NUMEROUS PROMOTION SCHEMES

There are numerous promotion schemes, large and small, in various portions of the State, and these tend to discredit the true conditions and thereby do great harm. The most noteworthy of these ventures is in Whatcom county, where a so-called anthracite deposit exists. Here the measures are tremendously broken and the coal has even passed the fuel point. Every condition there is against economic mining.

Considerable Japanese, Welsh, Australian and British Columbia coal has been used during the past year. Most of the steamers and the California markets have long since been forced to obtain coal elsewhere.

Experimental work in briquetting has been done with the coals of the Northwestern Improvement Company, the Snoqualmie Coal and Coke Company, and the Seattle Electric Company. Results as yet have not been successful. As gas producers, all the lignite coals are promising; they possess a large amount of gas and are cheaply mined.

The following new companies will, in the future, be large producers of Washington Coals: Mendota Coal and Coke Company, president, F. H. Ketcham, Centralia; Roslyn Fuel Company, president, Walter Oakes, Lournan building, Seattle. The output for 1908 will be approximately 3,000,000 tons; the output for the five years previous is as follows:

1903.....	3,190,477 tons
1904.....	2,905,689 tons
1905.....	2,846,901 tons
1906.....	3,290,523 tons
1907.....	3,712,172 tons

Wyoming Coal Industry in 1908

The greatest trouble experienced by the Wyoming coal operators in 1907 was due to the scarcity of labor and the lack of railway cars. In 1908, these difficulties were largely eliminated; however, the industry was confronted with a lessened demand which resulted principally from the decrease in traffic on the larger trans-continental railways. The output in 1908 showed but little change from the production of 1907. The total output sold for about \$10,370,000 at the mines. This was an average value of approximately \$1.70 per ton.

*Mining engineer, Seattle, Washington.

The Eastern Coal Industry in 1908

By JOHN H. JONES*

The year 1908 will show a production of coal in this country equal to about 85 per cent. of that of 1907, or approximately 400,000,000 tons, which is about equal to the tonnage produced in 1906. Had the increase in production not been so enormous during the past few years, this would have looked very large, and in fact is more than double that of 1897. During the recent depression the industrial centers suffered more than other localities, and the shipments to Pittsburg and the adjacent valleys were probably much more affected than any other section; the tonnage to these points showed a greater decrease than the domestic trade and what is known as the "Western" trade.

The conditions existing this year show the unfairness of freight rates from the Pittsburg district as against those from certain districts in West Virginia. Notwithstanding that this district, in 1908, will show only about 80 per cent. of its 1907 production, certain districts in West Virginia favored by cheap freight and mining rates, actually increased their production during the past year. If the Pittsburg district is to maintain its position in coal production, and to receive the proper returns upon the money invested in coal lands, the time is coming when a radical adjustment of the mining scale and freight rates must be made between certain districts in West Virginia, Illinois and other States, and the Pittsburg district. At the present time coal is being hauled three times the distance from parts of West Virginia and other districts at practically the same freight rate as from the Pittsburg region. This is an injustice and will have to be remedied.

Although certain companies in this district made low prices, the majority of them maintained a fair price throughout the season. By so doing, they lost considerable tonnage, but the wisdom of their position I think is emphasized by their ability to show a small profit instead of a deficit.

During 1909 it will be necessary for the Pennsylvania operators to secure higher prices for their coal on account of the increased cost of production, higher taxes and the greater cost which will be forced by new mining legislation which should and will be passed during the coming session of the Legislature.

FUTURE OUTLOOK IS ENCOURAGING

The prospects for the coming year look

encouraging and I feel confident that during 1909 the tonnage mined will equal at least 90 per cent. of the amount of coal produced in 1907. Many new propositions have been floated and many railroads have financed their requirements for some time to come. I think we are on the verge of the greatest industrial expansion the country has ever seen, but in my judgment, this improvement will be gradual and before the boom strikes us with full force we will be well on into 1909. The business of 1909 will, in my opinion, be so much better than that of 1908 that we will all be well satisfied. To keep up to the natural increase of consumption, it will be necessary to build new railroads, new manufactories, develop new mines and increase the production and manufacture of all the necessities of life. This means plenty of work for our workmen, increased buying capacity and prosperity for all.

The production of coal in this district for 1908 will be about 40,000,000 tons, which is about twice as great as the output in 1897, which was the banner year up to that time. The production for 1909 will be about 50,000,000 tons.

The settlement of the mining scale by the miners and operators for the two years from April 1, 1908 to April 1, 1910, lent stability to the business during the past year, and I believe was a good thing for both miners and operators, as a great industrial strike would simply have retarded the return of prosperity.

The lake tonnage from all districts for the eight years ending 1908, was as follows:

THE LAKE TONNAGE FOR PAST 8 YEARS.

Year.	Pittsburg District.	Ohio District.	W. Va. District.	Total.
1901	3,795,706	1,954,825	787,572	6,538,103
1902	4,704,093	2,689,974	965,769	8,359,836
1903	6,092,047	2,458,265	1,539,433	10,089,747
1904	6,058,383	2,138,247	1,279,876	9,476,506
1905	7,443,883	2,062,692	2,109,262	11,615,837
1906	9,287,272	2,560,906	2,743,732	14,591,910
1907	10,549,965	4,074,296	3,420,941	18,045,202
1908	8,700,000	3,600,000	3,450,000	15,750,000

From the above figures it is evident that there was a decrease in the Pittsburg district of about 18 per cent., in the Ohio district of about 12 per cent., and a small increase in the West Virginia district, which shows that other districts favored

by cheap mining and freight rates, are making great inroads into the markets which should really belong to the Pittsburg operators.

Every known method is being adopted by the majority of the operators of this country to provide for the safety and health of their employees. Mining experts from other countries have been called and consulted, and every appropriate suggestion carefully weighed with the opinions of the greatest mining experts of this country, before their introduction into the mines. During the past year many serious accidents have occurred in foreign countries as well as in this country, but I sincerely believe that with the benefits to be derived from our Testing Laboratory, and from the combined ideas of brain and skill, within the next two years, the Pittsburg district will show fewer lives lost per man employed than any other mining section in the world. At the present time, a less number of lives are lost per ton of coal produced, than formerly, as is shown by the accompanying tabulated statement.

In adopting new ideas, very often the welding of newer and stronger links makes the weaker ones in the chain more conspicuous, and what once appeared safe, now becomes actually dangerous. In years gone by, if there was an explosion in a coal mine, the air present was insufficient to render it serious; the gas would simply burn in suspension wherever it might be lighted, and do practically no damage. There have been and still are a number of unrecognized conditions in coal mines, but these conditions are rapidly being overcome.

I am satisfied that it is the earnest desire of every company in this country to do all possible for the health and safety of the men in their employ; moreover, all managers are glad to consider suggestions from a really intelligent source, as to the best methods of producing coal with the greatest safety to their employees.

A TAX UPON THE EMPLOYERS OF LABOR

During the past two years, I have recommended the placing of a tax upon

LIVES LOST PER TON OF COAL PRODUCED.

	Production (net tons).	Employees.	Tons Produced Per Employee.	Lives Lost.	Lives Lost Per Employees.	Lives Lost Per 1,000,000 Tons.	Days Worked.
Pennsylvania bituminous, 1903	103,713,982	151,743	683	402	2.65	3.84	216
Great Britain, bituminous, 1903	257,974,605	822,000	314	1072	1.30	4.15	264
Germany, bituminous, 1903	128,569,808	470,305	273	826	1.75	6.35	274
France, bituminous, 1900	34,123,901	158,580	215	224	1.41	6.56	296
Belgium, bituminous, 1902	25,217,835	131,889	187	144	1.06	5.71	289
Austria, bituminous, 1903	13,964,931	66,063	209	114	1.71	8.16	289

*President, Pittsburg-Buffalo Company, Pittsburg, Penn.

pay rolls of the employers of labor, this tax to be administered by a State commission, one-third to be appointed by the Governor and two-thirds to be elected by the people, the duty of this commission would be to administer the fund so collected and to see in case of death that the widow is cared for and the children are well educated and reared in the proper manner, and in case of an accident, not involving death, to pay to the injured person a weekly indemnity equal to the average weekly wage earned by him during the three years preceding. In other words, place a tax on the employers of labor sufficient to prevent their employees, and the wives and children of their employees, suffering from want due to accidents over which they had no control; this would place the injured in position to receive in case of such accidents money which would be due them under this law and which would not be administered as a charitable contribution. The disasters during the past year in blast furnaces, coal mines, railroads, etc., are evidence that we need such a law as suggested and need it badly.

The mining laws of the State of Pennsylvania say to the operators employing miners: "You must employ certificated mine foremen, certificated fire bosses, and place them in absolute charge of your mines. You must furnish them with all the supplies necessary for the operation of these mines, and your superintendents (practically meaning the owners of the mines) must not interfere with these men in the discharge of their duties." These are wise precautions on the part of the State to protect the health and safety of employees in and about coal mines, but notwithstanding all these great precautions, a number of serious disasters have occurred. It is certainly a fact that these State officials (known as mine and fire bosses) would not go into the mines and spend their entire time there, and permit the miners to continue operations if they did not consider the workings absolutely safe.

During the past year, we have made great strides in the knowledge of mining, but the personnel of the men in charge and the personnel of the men employed are an important factor in the safe working of coal mines. It is an old saying that "familiarity breeds contempt," and the fact that a man has done some thing a hundred times without observing the necessary care, and escaped injury, breeds within him a contempt for the danger and sometimes creates a reckless disregard for his own safety as well as the safety of others. This is the most difficult factor to guard against.

It is absolutely impossible to prevent all accidents in the mines, but what we must do is to figure out the best methods of reducing to the lowest degree the pos-

sibility of accidents. When we take into consideration that about 85 per cent. of the accidents in mines are due to causes other than explosions of gas and dust, or blown-out shots, and that more than 50 per cent. of these accidents could be prevented by care on the part of the persons injured, it is easy to see what good a more rigid police regulation in the mines will mean in the future production of coal in this country.

The mine inspectors of our State are clothed with police power. They are all practical miners, who, by their natural ability, have risen from the miners' ranks, and by study of mining conditions, have fitted themselves for the positions they now hold. They are making a special study of the best methods to protect the men under their care, and I feel confident that with the coöperation of the miners and operators of this country, we will soon be able to show a much lower ratio of accidents to the number of men employed.

Coal and Coke Production in the United States

The following table has been compiled largely from data communicated by the several State mine inspectors, estimates having been made only where no such statistics were available, but in all cases upon the basis of good information:

PRODUCTION OF COAL IN THE UNITED STATES.

States.	1907. Short Tons.	1908. Short Tons.
Bituminous:		
Alabama	14,417,863	11,950,000
Arkansas	1,930,400	1,750,000
California and Alaska	43,300	35,000
Colorado	10,920,327	9,773,000
Georgia and North Carolina	365,300	275,000
Illinois	(c) 31,317,146	48,000,000
Indiana	11,692,072	12,000,000
Iowa	(a) 7,568,424	7,650,000
Kansas	6,137,040	5,600,000
Kentucky	10,207,060	9,326,000
Maryland	3,529,663	3,000,000
Michigan	1,898,446	2,000,000
Missouri	4,350,000	3,900,000
Montana	1,810,000	1,800,000
New Mexico	2,302,062	2,725,000
North Dakota	(a) 268,300	250,000
Ohio	32,465,949	30,000,000
Oklahoma	3,450,000	3,250,000
Oregon	51,600	25,000
Pennsylvania	149,759,089	118,309,000
Tennessee	6,760,017	5,000,000
Texas	1,300,000	1,250,000
Utah	1,967,621	2,000,000
Virginia	4,370,341	4,000,000
Washington	3,713,824	3,000,000
West Virginia	47,205,065	41,091,000
Wyoming	6,218,839	6,100,000
Total bituminous	388,222,868	338,688,000
Anthracite:		
Colorado	45,113	30,000
New Mexico	17,000	10,000
Pennsylvania	80,279,719	80,240,000
Total anthracite	86,341,832	80,280,000
Grand total...	474,564,700	418,968,000

(a) For the fiscal year ending June 30.

(b) For the 12 months ending November 30.

(c) As reported by the U. S. Geological Survey.

PRODUCTION OF COKE IN THE UNITED STATES.

States.	1907. Short Tons.	1908. Short Tons.
Alabama	3,000,722	2,800,000
Colorado	1,007,051	854,000
Georgia and North Carolina	71,460	70,000
Illinois	372,697	270,000
Kentucky	77,055	60,000
Montana	31,400	30,000
New Mexico	203,437	260,000
Ohio	310,640	250,000
Oklahoma	57,600	50,000
Pennsylvania	23,516,309	11,287,000
Tennessee	495,200	250,000
Utah	324,692	200,000
Virginia	1,622,731	1,200,000
Washington	61,400	48,000
West Virginia	4,078,222	2,978,000
(Other states (c))	1,650,000	2,000,000
Total	37,066,619	22,697,000

(c) Includes output of by-product coke for Massachusetts, Maryland, Minnesota, New York, Michigan, Wisconsin, New Jersey.

If the production of coal in 1908 had shown as large an increase as in 1907, the long predicted half-billion total would have been reached. To satisfy our fuel demands during the last 12 months, we have exhausted about 61 square miles of our available coal lands. If our production should remain stationary, at this total, in future years, it would require over 6000 years to exhaust our coal beds; if, however, the future production should increase at a rate equal to that shown in 1907, the available coal seams would last only about 200 years.

Mineral Output of Japan

The following table, taken from the *Yokohama Chamber of Commerce Journal*, shows the output of various minerals in Japan during the six months ending June, 1908, and the corresponding period of 1907:

	1908.	1907.
Gold.....	297,301 momme ¹	305,098
Silver.....	14,129,593 momme ¹	10,820,357
Copper.....	28,474,318 kin ¹	27,718,190
Iron.....	4,954,794 kwamme ¹	5,779,875
Coal.....	5,945,718 tons	5,793,896
Kerosene.	703,308 koku ¹	723,046
Sulphur.....	19,392,554 kin	18,570,893

COPPER EXPORTS

The export of copper to foreign countries during the first half-year is stated to be 28,630,000 kin worth 10,700,000 yen.¹ The following table shows the quantity and value of export for the last three years:

	Quantity. Kin.	Value. Yen.
1905.....	34,640,000	16,440,000
1906.....	56,670,000	25,100,000
1907.....	53,450,000	29,260,000

The copper is chiefly exported to China, Hongkong, England, France, Germany, and America.

¹ 1 momme = 57.97 grains; 1 kwamme = 8.28 pounds; 1 kin = 60.04 grains; 1 koku = 39.68 gallons; 1 yen = 28.058d., or 49.95 cents.

The Petroleum Industry of the United States

Production of California, Texas, Louisiana, Lima, Illinois, Mid-continental and Appalachian Fields. Developments in Various Districts

PRODUCTION, 184,734,678 BARRELS

As shown in the accompanying table, the production of crude petroleum in the United States during 1908 showed a large increase over that of 1907.

PRODUCTION OF CRUDE PETROLEUM IN THE UNITED STATES.

(IN BARRELS OF 42 GAL.)

Field.	1907.	1908.
California	40,085,000	43,000,000
Colorado	400,000	(a) 400,000
Gulf	12,330,000	11,904,000
{ Texas	4,620,000	5,896,000
{ Louisiana	24,540,024	38,000,000
Illinois	8,030,000	7,287,000
Lima	47,556,906	50,741,678
{ Ohio	1,250,000	(a) 1,250,000
Mid-continental (c)	25,500,000	24,340,000
Kentucky-Tennessee	3,000	(a) 13,000
Appalachian (d)	3,000	(a) 13,000

California

When California was producing about 20,000,000 bbl. of petroleum per annum, and the prices at the wells were around 20c. per barrel, it was considered that there was an overproduction, owing to the fact that consumption did not keep pace with the gradually increasing yield. In fact at that time many productive wells were capped because the prices were unsatisfactory and a ready market was not found except for the product of the larger companies which had commercial or business facilities for disposing of their oil in a profitable manner. There was some uncertainty as to continuance of supply and difficulty in delivery at specified time. Probable consumers were afraid that they would be unable to obtain the necessary supplies regularly, and continued with their old systems. The railroad companies hesitated to put large amounts of money into oil cars when they knew that eventually pipe lines for oil transportation would be built, and the cars would become useless. The shortage of oil cars for this reason prevented developments which were contemplated in the various fields.

These conditions have changed. Pipe lines have been built not only from the valley fields to tidewater, but also from the various fields to the main lines, and even to productive individual wells. The demand has increased with the production, so that even with the more than doubled output and the trebled price all the oil which is produced is readily dis-

posed of. In virtually all the large railroad manufacturing and power enterprises of the State, fuel oil has displaced coal in the boilers. As a steady supply of oil is assured, there is no hesitation in making contracts for steady supplies, with no fears of interruption or necessity of changing back to old systems of firing.

While there has been a great increase in the consumption of fuel oil, there is little increase shown in the output or consumption of by-products. The revival of the various manufacturing interests of the State since the great disaster in 1906 and the resultant increase in the business of the railroad companies form two of the most important factors in the increased demand for fuel oil. A few years ago 30 per cent. of the cars were laid up on the main railroad lines for lack of business, but now all are in use, requiring many more locomotives and causing a greater consumption of fuel oil. In the steamship business much larger quantities of fuel oil are now used than formerly, while the rapid multiplication of industrial enterprises and the demand throughout the State for power for various purposes has also increased the use of fuel oil.

California is now producing about 45,000,000 bbl. of oil a year, that being the estimated output for 1908. In 1907 the yield was 39,748,375 bbl. valued at \$14,699,956, or about 37c. per bbl. In 1906 the average prices was 29c. per bbl. In 1908 the average price at the well to the producers was about 50c. per bbl., and at the end of the year it was perhaps higher than 60c. per bbl. All the old contracts have been "worked up" and the new ones being made vary from 50c. to 63c. per barrel.

As this is very encouraging to the oil men, every effort is being made to enlarge the output. In 1908 some of the companies nearly doubled the yield of the previous year; much prospecting is going on in undeveloped territory and new wells are being sunk in proved areas. Indeed had the daily yield of all the wells of the State continued throughout the year in the same proportion as it was in October and November, the total output for 1908 would have exceeded 50,000,000 bbl. The daily output was in those months about 140,000 bbl. The Kern River field heads the list in amount of daily production, followed in order by Coalinga, the Lom-

poc and Santa Maria, and the Los Angeles-Salt Lake fields. In the Kern River field there are 1090 producing wells which average 35 bbl. a day per well. In Coalinga there are 385 wells yielding an average of 80 bbl. a day per well. In the Santa Maria field the wells are averaging a daily product of 200 bbl. a day per well. In other fields the flow from the producing wells varies from 20 to 70 bbl. per day.

In 1907 there were 2630 wells which were producing but the figures for 1908 are not yet available. When the entire number of productive wells in a field is considered, the average daily production per well is not nearly as high as many persons imagine. Some will run high and others low, but, when the sum total is added, the aggregate may become quite large. For example, in 1907 the Kern River field had 840 productive wells, which averaged a daily yield of 40 bbl. a well. The average of a smaller number of wells in the McKittrick field was 102 bbl. per day and in the Midway, the average was 87 bbl. while it was only 47 bbl. in the Sunset field. At Coalinga 247 wells averaged 99 bbl. a day per well. At Santa Maria and Lompoc combined the average per well was 291 bbl. per day, there being 80 wells in the field. At Santa Paula and Newhall the average was 4 bbl., and in the Salt Lake field of Los Angeles 80 bbl. per diem.

DEVELOPMENT DURING 1908

The increase in consumption of California fuel oil in 1908 is general and is from 20 to 25 per cent. over the amount in 1907, both for industrial and railroad uses, and the output is expected to keep pace with this. In one field alone—the Kern River—there was in 1908 an increase of 25 per cent. in the number of productive wells compared with the number in 1907 and, while the increase is not so large in other fields, yet there is an apparent increase in all, with the possible exception, perhaps, of the Santa Maria field which has not quite "held its own." In that field a large amount of water is being pumped with the oil, and it has not been found possible thus far to shut this water off.

A great deal of "wildcat" drilling is going on in most of the fields, especially between Coalinga and Sunset, but there are possibilities of opening up a great production in that region. In the Mid-

way field in Kern county somewhat lighter oils are obtained in the wells at some distance from the area where the outcrops are. In the Monterey County region where much prospecting has been done lately there is as yet no production to note. The drilling in that vicinity is hard and slow for there is much granite drift to pass through.

The pipe line 280 miles long, from the Kern river field to Port Costa, at tidewater, was completed in 1908. It is an 8-in. rifled pipe line owned equally by the Associated Oil Company and the Southern Pacific Railroad. Between Bakersfield and Port Costa there are 12 pumping stations, for both water and oil, on this line. The "rifling" of the pipe gives it a much greater carrying capacity with heavy fuel oil, than an ordinary smooth-bore pipe has. This is the second pipe line from Kern county to tidewater.

The Associated Oil Company intends building another pipe line from Sunset on through the Midway, the McKittrick, and the Devil's Den fields to Coalinga. The fields in Santa Barbara county have their pipe lines to the ocean, and there is one from Fresno county to Monterey bay.

The average California oil is quite heavy, with an asphalt base, and lighter oils for local purposes are greatly in demand. Many rigs are at work prospecting for low-specific-gravity oils in what are considered likely regions. This light oil is needed for refining purposes.

The Japanese are large consumers of California fuel oil; and have extensive contracts, mainly with companies owning wells in the Santa Maria field. It is understood that they would take 10,000,000 bbl. yearly if that quantity could be guaranteed for delivery at satisfactory prices. They have some fear, however, that the amount desired could not be supplied regularly at stated periods. There is at present in California a party of Japanese oil experts looking over the different fields, and investigating their ability to supply the Japanese demand. There is some talk of these Japanese buying out entirely certain productive fields or companies.

The owners of productive wells in California are quite independent, for they have an assured market and get good prices for their oil. In the valley fields when a good productive well is struck they can, without much difficulty, get someone to build a branch pipe line to it. They are not dependent on a refining company, for their fuel oil does not have to be handled by others to become a marketable product, as is the case with illuminating oils. They get the ground, dig the well, and get out the oil in the same way relatively that the farmer gets his crop. As soon as the oil is pumped it is salable, and there are plenty of

people ready to take it, or make future contracts for it. Moreover, there are a number of California capitalists ready and willing to invest in oil and oil lands, to develop territory, to build pipe lines, etc. Under these circumstances no one company can control the various fields and fix prices. For these reasons the owners of oil wells are becoming particularly independent, and self-reliant.

THE OUTPUT OF THE LEADING COMPANIES.

The various oilfields are gradually being enlarged as new wells are sunk and developments progress. All have now good transportation facilities to tidewater, and large refineries are numerous. A great amount of prospecting is being done in new sections which promise good results, and much money is thus being expended in finding new oil-yielding areas. Meantime, in the older fields more extensive operations are being carried on, and deeper explorations are being conducted.

The California Stock and Oil Exchange of San Francisco, in its monthly statement of dividends paid by active listed California oil companies for the month ending Nov. 30, 1908, gives the following:

Total dividends paid to date: Alma, \$136,800; Amalgamated Oil, \$800,000; Apollo \$4,000; Associated Oil, \$1,522,309; Brookshire, \$322,500; Caribou, \$377,720; Chicago Crude, \$15,000; Claremont, \$107,000; Coalinga Pacific, \$30,000; Columbia, \$134,886; Esperanza, \$20,650; Euclid, \$68,000; Four, \$185,000; Globe, \$5,100; Hanford, \$80,000; Home, \$442,000; Homestake, \$60,250; Illinois Crude, \$48,000; Imperial, \$1,040,000; Junction, \$2,500; Kern River, \$20,000; Linda Vista, \$26,870; Lucile, \$8311; Monte Cristo, \$265,000; Nevada County, \$40,000; Peerless, \$741,000; Piedmont, \$11,317; Final, \$504,841; Pittsburg, \$124,800; Reed Crude, \$1,107,000; Rich Ranch, \$60,000; Royalty, \$200; S. J. & McKittrick, \$75,000; Sauer Dough, \$320,175; Sovereign \$65,000; Sterling, \$247,000; Superior, \$30,000; S. W. & B., \$15,080; Thirty Three, \$60,000; Union, \$4,420,000; United Petroleum, \$1,532,952; Wabash, \$72,000; West Shore, \$225,000; Western Union, \$484,951; total dividends paid to date, \$17,393,772; total dividends paid by the above companies for November, 1908, \$358,220.

The total dividends paid up to date by some California companies not listed on the Exchange to date, as copied from other official records are: California Oil Fields, Ltd., \$1,750,000; Central, \$483,926; Continental, \$15,000; Fullerton, \$142,000; Olig Land Company, \$13,000; Olig Oil Company, \$15,000; Olinda Land Company, \$40,000; Persens Oil Company, \$13,564; total, \$2,756,490; grand total, \$20,150,262.

Illinois

By H. FOSTER BAIN*

The oilfields of Illinois produced in 1908 a little less than 40,000,000 bbl. of petroleum. The returns for the year are not complete, but, estimating the December production as equal to that of November and that the tank-car shipments were very little more than in 1907, a total of 38,000,000 bbl. may be given as the approximate figure for 1908. The detailed pipe-line runs and miscellaneous receipts of the Ohio Oil Company for the first 11 months of 1908 are given in an accompanying table.

RECEIPTS OF THE OHIO OIL COMPANY, 1908.

	Pipe-Line Runs, Bbl.	Other Receipts, Bbl.	Total, Bbl.
January	2,407,914	98,433	2,506,347
February	2,464,914	228,004	2,674,918
March	2,591,911	191,963	2,783,874
April	3,089,417	439,709	3,529,126
May	3,084,815	1,015,263	4,100,078
June	2,965,786	917,741	2,913,527
July	2,379,977	301,000	2,881,067
August	2,690,631	1,059,941	3,750,572
September	2,555,871	744,125	3,299,996
October	2,582,561	395,818	2,978,379
November	2,356,385	318,552	2,674,937

The bulk of the miscellaneous receipts consists of oil purchased in tanks when leases were transferred. No additional lines have been laid into the field though the Pure Oil Company is now laying a line to connect with the Tidewater line. The Indian Refining Company, the Sun Oil Company, the Cornplanter Oil Company, and the Robinson Oil Refining Company continue to ship in tank cars. As in past years production, except for a short time in May and June, ran ahead of the capacity of the pipe lines. For most of the season approximately 60 per cent. of the oil offered was taken. The price remained fixed at 68c. per bbl. for all oil above 30 deg. B. and 60c. per bbl. for that below 30 deg. B. The great bulk of the oil was marketed at the higher rate. On Dec. 1 the gross stock of the Ohio Oil Company amounted to 24,930,030 barrels.

DEVELOPMENT DURING 1908

The principal development work of the year was in Crawford, Lawrence and Clark counties, the largest wells being found in the deepest sands. Within the year Coles county, after repeated failures, became a producer. Drilling was active in the early summer, but the severe drought crippled operations in the fall.

On Jan. 1, 1908, it was estimated that 9772 wells had been put down. Of these 1260 were dry holes. In the first 11 months of 1908, 3290 wells were drilled, with 513 dry holes and 72,353 bbl. of new production. The record by months, taken as heretofore from the

*Director, State Geological Survey, Urbana, Ill.

Oil City Derrick, is given in an accompanying table.

WELLS DRILLED IN ILLINOIS DURING 1908.

	Average Initial Production.	Wells Completed.	New Production.	Dry Holes.
	Bbl.		Bbl.	
January	243	383	6144	55
February	24	157	3329	22
March	273	187	4338	37
April	26	107	4855	33
May	29	264	6628	35
June	29	390	9866	54
July	25	471	9475	65
August	23	417	8322	55
September	26	344	7848	49
October	26	290	6091	51
November	29	273	6242	51

The drilling record for 1908 in southeastern Illinois, summarized by counties, is given in an accompanying table.

WELLS DRILLED DURING 1908 IN DIFFERENT COUNTIES, ILLINOIS.

County.	Wells Completed.	New Production, Bbl.	Dry Holes.
Crawford ..	2024	40,326	289
Lawrence ..	601	19,405	63
Clark	321	5,996	66
Casey	7	91	2
Edgar	7	15	1
Miscellaneous ..	27	10	25

Outside the old oil district "wildcatting" continued active throughout the year. The principal result was the bringing in of enough wells to start production at Sparta in Randolph county. Here the Sparta Oil and Gas Company made up of St. Louis people, has a group of wells a short distance east of the old gasfield. The oil comes from the Chester formation. After finding several 5- and 10-bbl. wells, one was shot which is said to have come in at 135 bbl. a day. The oil is shipped in tank cars and through field lines; approximately 50 bbl. a day are going out. Numerous other wells are being drilled in the vicinity.

IMPORTANCE OF THE CENTRALIA FIND

On Nov. 1 a well was brought in at Centralia in Marion county. Oil had been found here seeping into a coal mine along a fault plane. The well was drilled a short distance east of the mine; at about 600 ft. a good sand was found in the coal measures. After shooting, the well settled down to an 18-bbl. pumper. Numerous other tests are now being drilled in the vicinity. The significant points in this find are that Centralia is well toward the center of the great structural basin of southern Illinois and that the sand is of approximately the age of the Casey sand in which oil was first found in Clark county. This geological horizon is widespread, but as yet it has not been found productive in many places.

Small amounts of oil and gas continue

to be found at various points along the western edge of the basin, but so far without any important commercial result. The year as a whole has been quietly prosperous, and the outlook for 1909 is excellent. In 1908 there was no especial change in the situation as regards the production of natural gas.

Texas and Louisiana

SPECIAL CORRESPONDENCE

Nothing but the expected happened in the gulf, coastal and north Texas fields during 1908. Field operations declined, and while two new gusher fields were threatened, fortunately (most persons think) they did not materialize.

The Anse Le Butte district, which in 1907 seemed to promise a large output, simmered down, after the expenditure of a large sum in development, to the original discovery well and a few others in the immediate vicinity. Markham and Goose creek discoveries sent declining crude-oil prices to the lowest point of the year, only to prove a false alarm. Caddo slowly increased its output and prevented the coastal field from showing a decline in production.

Old districts were in some cases extended in area, and held up their production better than expected, so that the yearly output was satisfactory, in spite of the fact that Jennings during November reached its lowest output for many months.

While prices declined very much they were a fair reflex of conditions and above the normal when compared with mid-continent fields.

OUTPUT

The 1907 production in Texas was 12,322,606 bbl., of which 11,410,078 bbl. was derived from the coastal region. The Louisiana production for 1907 was 5,000,221 bbl. and the total coastal field output, 16,410,299 bbl. The 1908 estimates for Texas, as nearly as can be stated at the present time, are 11,904,000 bbl., of which about 10,010,400 bbl. is credited to the coastal field. The Louisiana output is placed at 5,836,000 bbl., making the total for the coastal field 17,000,000 bbl. The figures are only approximate, for the north Texas and the December output of the coastal fields are not definitely known.

The figures given above indicate a decrease of 418,000 bbl. in Texas, half of which is attributed to coastal fields, while Louisiana shows an apparent increase of 895,500 bbl., occasioned by the added output of Caddo and Anse Le Butte.

The selling price of crude varied greatly and was so much lower than in 1907 that the total value declined from \$14,-

000,000 in 1907 to about \$10,500,000 in 1908. Wildcat drilling was generally confined to local owners of land and State corporations, for oil operators who make a regular business of exploiting prospective oil territory were engaged in the mid-continent field, where the percentage of dry holes proved less than in Texas.

According to the *Oil Investors' Journal*, the number of completed wells in the coastal field in the 11 months to Dec. 1 was 748, of which 359 were oil producers, 21 gas wells and 168 dry holes. The record for a similar period in 1907 was 681 producing oil wells, 21 gas wells, and 213 dry holes.

In north Texas to Dec. 1, 1908, 65 wells had been completed, of which 20 were dry. The 1908 figures do not include those wildcat wells outside of the Markham and Goose creek fields, and the gas wells were mainly in the Caddo field though Humble and Henrietta contributed a few.

Jennings was again the largest producer, having an output of approximately 4,960,000 bbl. The production of the other leading pools was as follows: Humble, 4,011,000; Spindletop, 1,814,000; Sour Lake, 1,791,000; Saratoga, 1,774,000; Batson, 1,543,000; Caddo, 615,400; Anse Le Butte, 280,000 bbl. Other small producing pools were Markham, Goose Creek, Mission, and Welch. In north Texas Powell was the largest producer, followed by Corsicana and Henrietta.

COMMERCIAL CONDITIONS

The crude market opened weak in 1908 and the use of weathered crude from Oklahoma and northern Texas further depressed prices early in the year, so that the posted credit-balance prices (which may be taken as the base price paid consumers) ranged from 67 to 75c. The quotations compared favorably with those of 29 to 41c. per bbl. paid in Oklahoma, when the quality of the crude is considered, although it must be borne in mind that for fuel purposes (practically the sole use of coastal crude) an oil of 18 to 20 deg. B. is better than that of 30 to 32 deg. B.

The undoubted effect of high crude-oil prices in 1907 was shown in the 500,000-ton increase in the coal output of Texas for that year where previous years had shown a decline.

Quotations declined in March, April, and May, until the highest price posted was 60c., and in June the Gulf and Texas companies suspended quotations, while the Sun Company prices ranged from 38 to 42c., a decline of more than 100 per cent. Stocks were increasing, demand was poor, and there was general uneasiness regarding the capacity of the new pools at Markham and Goose creek.

Buying by cotton compressors, sugar plants, and by the railways, combined

with the failure of the new pools and the operations of the Oil Producers Marketing Company raised the posted prices gradually to 55 to 57c. in October. Since then the market has remained weak. There is no valid reason for any advance in the near future unless production declines greatly, when local conditions may warrant higher prices.

If the proposed Prairie Oil and Gas Company pipe line from Oklahoma to New Orleans is constructed, a market now exclusively supplied by coastal crude will be divided and consumption further reduced. The preliminary survey of 520 miles for this line has been made, and all the interested Oklahoma municipalities have consented to the crossing of their highways. Under existing and probable future conditions coastal producers will be fortunate if the average price for 1909 equals that for 1908, which was about 60c. per bbl., compared with 84c. in 1907.

These prices do not apply to the Caddo field, the oil from which is not taken by the Southern pipe lines, but has been shipped by tank cars and for which recent prices have ranged from 35 to 38c. per bbl.

It became known during the year that the amount of crude carried as stored oil was much too large. The quantity deducted for evaporation, seepage and field consumption during the last few years was much too small, most of the discrepancy being occasioned by the extended use of crude in operating the large air compressors in the Jennings pool.

Careful investigation by the *Oil Investors' Journal* placed crude stocks on Oct. 1 at 3,130,000 bbl., and the amount of stocks on Dec. 31, was approximately 3,200,000 barrels.

LEGISLATIVE AND JUDICIAL PROCEEDINGS

The suits instituted by the State against the Standard Oil Company, Security Oil Company, Union Tank Line Company, and other alleged affiliated corporations resulted in a receiver taking charge of the Union Tank Line Company cars, which were promptly leased to one of the railways. The Security Oil Company succeeded in obtaining relief from the vexatious conditions of the injunction proceedings, and its large refinery near Beaumont was put in operation again in January. The suits which are for ouster and for penalties amounting to many millions with the customary collateral garnishee proceedings drag along subject to the usual legal quibbles and delays.

The protests against the burdensome Kennedy gross tax laws continued, but most operators paid the tax, only one or two, including the Southwestern Oil Com-

pany of Houston, are testing the constitutionality of the act.

LOUISIANA DISTRICTS

Production in Louisiana was confined entirely to fields located prior to 1908, although wildcats were drilled in Rapides, Webster, Terrebonne, Winn, Saint Landry, and Calcasieu parishes during the year. The Welch pool remains small and practically no effort was made to develop it.

The Jennings pool was extended about a half mile westerly, the most important development since the Latrille 40-acre extension in 1907. Many of the new wells had an initial flowing output of 3000 to 5000 bbl. daily. After a brief period compressed air was used on them giving a much larger output than they would have yielded under the pump. The pool is not only the largest producer in Texas or Louisiana, but also leads in average production per well.

More than 50 new wells were drilled in 1908, but the last months of the year show a rapid decline in field operation and production. The maximum output of Jennings was 557,000 bbl. in March and the minimum, 320,000 bbl. in November.

The Anse Le Butte pool proved a disappointment, despite active work and a very large expenditure of money. Salt water is the greatest detriment encountered, and the few producing wells are confined to those in the vicinity of the original well drilled by the Lake Oil Company. The average daily output does not exceed 1000 bbl., and the production for 1908 was about 280,000 barrels.

Caddo field operations were gradually extended during the year, and this pool will certainly be the most active one in Louisiana during 1909; 50 wells were completed up to Dec. 1, 1908, and the total output is estimated at 615,000 bbl. The proved field now extends over an area of many square miles and both the United States and State Geological Surveys are investigating its resources and geology. Conditions are radically different from those of the large gusher fields of the coast (which are of small area) and will be more slowly developed. While the gas wells are of large capacity the oil wells are small producers when compared with those of Spindletop, Saratoga, or Humble. Drilling is expensive in addition to being slow and hazardous on account of the enormous gas pressure usually found in the overlying strata at 820 to 940 ft. Most of the producing oil wells are in the 2200 to 2275-ft. sand, although there are several in a sand at 1580 ft. The gravity of the oil varies from 24 to 30 deg. B., and the initial production runs from 100 to 400 bbl. per well.

The output in January, 1908, was only

8000 and gradually increased to 90,000 bbl. in December.

TEXAS DISTRICTS

Humble and Spindletop were the only pools showing an increased output as compared with 1907. Humble's large production was caused by active development in the northern extension of the proved field. Completed wells to Dec. 1, aggregated 234, a number three times as large as in any other Texas field. The average initial capacity of the wells was also greater than in any pool outside of Jennings.

Spindletop production increased slightly, and field work was more extensive than at Batson or Saratoga. The only feature at Sour Lake was the expanding of the proved area 450 ft. easterly, while at Saratoga drilling into the deeper sand at 1490 ft. prevented a more serious decline than would otherwise have occurred.

The small pools at Mission, Liberty, Dayton, and Piedras Pintas were only notable for inactivity and their output was confined to a few wells of limited capacity.

In Clay county, northern Texas, some excitement was caused by the bringing in of a few oil wells of larger flow than usual. Gas wells of great volume were also located and are being utilized by the Navarro Refining Company to supply the cities of Henrietta and Wichita Falls, with a probable extension of the pipe line to Dallas and Fort Worth.

None of the wildcat wells scattered through Texas created anything more than local interest other than those located at Markman and Goose Creek. The first-named field is in Matagorda county, 6½ miles northwest of Markham, a station on the Victoria division of the Southern Pacific Railway. The topography of the district is similar to that of other coastal fields. Gas seepage induced the Hardy Oil Company to drill a well which was brought in early in June at a depth of 1370 ft. The pay sand resembles that at Jennings, the gravity of the crude is 22 deg. B., and the initial capacity of the well was about 80 bbl. per hour. The Rio Bravo Oil Company (Southern Pacific Railway) promptly laid a pipe line to the railway and contracted for the output at 50c. per bbl. Another well of smaller capacity was soon brought in, but subsequent field operations by the Guffey Company and others extended over a wide area failed to find any extension of the pool. Production soon fell off and in consequence of the failure to "make good" the field is practically idle at the present time, although there is a bare possibility of its developing into a fair producer. The output to date has been about 60,000 barrels.

Goose Creek, the other discovery which

gave promise of being another gusher field, was located about the same time as Markham. The territory lies in Harris county, 25 miles east of Houston at an altitude of 30 ft. above the level of Galveston bay, and only a mile distant from the barge channel. The discovery well was the third test hole drilled by Armstrong, Peden & Co., the second well having yielded a small amount of oil which was utilized for fuel. Well No. 3 was finished at 1600 ft. (much deeper than usual in similar formations along the coast) and yielded about 700 bbl. daily, of 18 deg. B. gravity crude. The Producers' Oil Company acquired the producing property and drilled about ten wells to determine the area of the field. All these holes proved dry except one or two in the immediate vicinity of well No. 3. Several wells are now going down, but most operators have formed an unfavorable opinion regarding their success, although their opinion may be fallacious. The Texas Company has laid a pipe line to the barge channel, so that water shipments can be made, but the output so far is merely nominal.

FUTURE PRODUCTION

It is unlikely that the Texas-Louisiana production will decline materially in 1909, for while the old fields are failing they are still capable of development and will be actively worked. Caddo will surely increase its output and make up largely for the deficiency in other fields. There is also the possibility that Markham and Goose Creek will develop into fairly good fields, although it must be admitted that operators are pessimistic.

It is to be hoped that no very large pools will be discovered in the near future, for the present supply fully equals consumption in local markets and a new gusher field would cause a fall in crude prices demoralizing to producers in the old pools.

Oil and Gas in the Mid-continental Field

By ERASMUS HAWORTH*

During the year 1908 no remarkable developments were made anywhere in the Mid-continental field, either in oil production or gas production. Drilling was greatly diminished compared with either of the previous two years. Nevertheless, many rigs were in operation almost constantly and in the aggregate a great many new wells (something more than 1600) were brought in. In Oklahoma drilling was confined principally to a search for oil, and, therefore, gas developments in the main were incidental, while in Kansas

more than half of the drilling was done expressly in a search for gas.

OIL

Drilling was continued practically in every district in Oklahoma, particularly in the Glenn pool area and the Alluwe shallow pool area. The Glenn pool remained the largest producer, aggregating 50,000 bbl. daily throughout the year. The Alluwe area was greatly extended northward and its total production materially increased. Production in the vicinity of Dewey, and generally throughout the Osage, declined. Scarcely a well was drilled for oil in Kansas, and the production in this State was greatly reduced. Numerous wells are standing idle which would produce in the aggregate large amounts of oil were prices better, but with the ruling low prices they would not pay to operate.

(Standard) again was the principal purchaser of oil, although not so emphatically so as previously. The company's total runs aggregated 33,181,951 bbl., the December runs being estimated, which gives a daily average of 90,661 bbl. Of this amount 25,273,941.54 bbl. were delivered to the refineries, the remainder going to storage. At the end of the year the Prairie Oil and Gas Company, therefore, had a total storage of 38,971,913 barrels.

The largest independent purchasers of oil were the Gulf Oil and Pipe Line Company and the Texas Oil Company, each of which purchased more than 5,000,000 bbl. The independent refineries are on the increase and this year consumed perceptibly more oil than the same class of refineries did in 1907. A number of other firms shipped large quantities of oil by rail from different points in Oklahoma.

Totals for year	50,741,678

PRICES.

No change whatever occurred in the prices of crude oil throughout the year; oil of 32 deg. B or lighter brought 41c. regularly. During the year oil prices in Indiana, Ohio, West Virginia, and Pennsylvania had slight fluctuations, the highest price paid in Pennsylvania reaching \$1.78; Lima, Ohio and Indiana oils, around \$1; Kentucky oils, \$1; Corsican, Texas, light oils, 70c.; heavy oils, 48c.; Illinois regular, 68c.; and under 30 deg. gravity, 60c. Why such a great discrimination is made by the large purchasers of oil in the Mid-continental field is known only to the purchasers the selves. Probably the public would all guess in the same direction, i.e., that the low price is maintained simply because it is in the power of the purchasers to maintain it. It was hoped by the producers that when the independent pipe lines were put in operation, prices would be advanced, but no apparent change resulted.

PRODUCTION.

The Prairie Oil and Gas Company

the more important shipments being made by W. G. Barnes, Haywood Oil Company, Quaker Oil Company, W. H. Milliken, Laurel Oil Company, Benson Oil Company, Kansas-Oklahoma Oil Company, Superior Oil Company and a few others shipping smaller amounts.

To all of these sums must be added the amount of crude oil used for fuel, which was fully as great as in any previous year. In the following estimates no account was taken of the amount of oil stored by the producers. It is probable that the total storage in the field at the end of 1907 was as great if not greater than at the close of 1908. The figures included in the following tables, therefore, are for the actual deliveries to purchasers. These tables summarize the entire statistics for the year. It should be noted that there is a slight discrepancy in the figures given out by the Prairie Oil and Gas Company, the amount put in storage plus the deliveries not being quite equal to the total runs. The error evidently was an unintentional one, but suf-

*State geologist, Lawrence, Kansas.

ficient data were not at hand to make the slight corrections desirable.

REFINERIES.

Of the refineries using oil from the Mid-continental field those of the Standard at Neodesha, Kan., and at Sugar Creek, near Kansas City, are much the greater. They consumed the principal part of the 25,000,000 bbl. delivered by the Prairie Oil and Gas Company, the remainder going to the large refineries at Whiting, Ind. At the present time 25 different independent refineries are in existence, 17 in Kansas and eight in Oklahoma, all of which are in operation excepting four; two of these are closed down temporarily and the other two not quite completed.

These 25 refineries have an aggregate annual capacity of more than 3,500,000 bbl. consumption, and are located as follows:

Oklahoma: Big Heart, one; Chelsea, one; Muskogee, one; Oklahoma City, one; Okmulgee, one; Sapulpa, one; Tulsa, two (one closed down).

Kansas: Atchison, one (closed down); Caney, one; Chanute, four; Cherryvale, one; Coffeyville, three (two not yet completed); Erie, one; Humboldt, one; Longton, one; Moran, one; Niotaze, one; Paola, one; Petrolia, one.

The refinery at Paola changed hands late in 1907, at which time it was reported that it was bought by the Standard Oil Company. Since then this report has been denied, and at present the public is uninformed as to where the ownership lies. These independent refineries consumed a little more than 3,000,000 bbl. of oil during 1908.

FUEL OIL.

A large amount of fuel oil is used in the great-plains area of western Kansas, Oklahoma and Texas, and eastern Colorado and New Mexico, a large proportion of which is drawn from the Mid-continental field. Some of it is taken directly from the wells, the remainder being supplied by the refineries after the lighter oils have been removed.

The plains area in general consumes but little fuel; yet in the aggregate it amounts to 4,000,000 to 5,000,000 bbl. annually. It is used by almost every flouring mill, ice plant, electric light plant, and other plants generating steam throughout the entire territory of the plains area where coal is high priced, it having been found that oil is cheaper than coal, especially on account of the lower labor cost involved in its use. Such a large consumer even as the portland cement plant at Yocemento, Ellis county, Kan., finds it advantageous to use oil for fuel.

GAS

But little change occurred in the gas situation in the Mid-continental field dur-

ing the year. At the present time the consumption in Kansas is exceedingly large, while that in Oklahoma is but little more than a year ago.

In Kansas the Kansas Natural Gas Company is the largest consumer. The principal addition to its pipe lines during the year 1908 was in a greater extension of the service in Kansas City, Mo. At the close of 1907 less than half of Kansas City was supplied with natural gas, but before the winter season had passed the greater part of the city was reached with the supply pipes. Pipe-laying was continued during the summer so that at the present time practically all of Kansas City and its suburbs are supplied with natural gas from the Kansas fields. Here is a city which, including Kansas City, Kan., and all suburbs, has a population of nearly 400,000 using natural gas for domestic purposes. Nearly all of the smaller factories use it, while some of the larger factories employ the gas during the summer season.

The supply pipe lines were also considerably extended in the Joplin zinc mining district, thus reaching hundreds of consumers which were not supplied with gas during the year 1907. The Kansas Natural Gas Company's pipe lines extend east from the gasfields as far as Joplin, Mo., and supply gas to every town and village along the line, including Parsons, Oswego, Cherokee, Pittsburg, Baxter Springs, Galena, Joplin, Webster City, Carterville, Carthage and many other places. The company's pipe line also extends north from the gas fields to Lawrence and Topeka, to Leavenworth, Atchison, St. Joseph, Mo., and Kansas City. During the year 1907, according to official statements of this company, the income from sale of gas was a little more than \$3,000,000. For the year 1908 it will aggregate about \$4,000,000.

THE SUPPLY

A great deal of complaint was made last winter at Kansas City about the insufficiency of the supply of gas. Similar complaints were made from St. Joseph and Topeka, but to a much less degree. The gas company answered such complaints with the statement that large pumps, which would guarantee an abundant supply in the gasfield were in process of being installed; during the latter part of the winter and throughout the summer of 1908 a large pumping plant was installed at Scipio, a few miles north of Garnett, Kan., and another large one in the heart of the Montgomery County gasfields, five or six miles south of Independence.

The months of November and December, 1908, were so mild that no opportunity

offered for testing the adequacy of these pumps. It is hoped, however, that they will prove sufficient to supply all the gas that may be needed in the near future.

The second largest consumer of gas in the Mid-continental field is the Wichita Gas Company, which has laid a pipe line from the Montgomery county field westward to Winfield, Arkansas City, Wichita, Hutchinson and other towns in south central Kansas. This company has holdings in Oklahoma but obtained the main part of its gas from the Montgomery County fields, picking up a very considerable amount from various wells in Chautauqua and Cowley counties. In addition to supplying practically every residence and business house in the various towns and cities reached by its line, the company also supplies the smaller manufacturers and to a considerable extent the salt plants at Hutchinson and Sterling, where large quantities of evaporated salt are produced.

The zinc smelters and portland cement plants come next in quantity of consumption, particularly the cement plants. The year 1908 was not a very prosperous year for zinc smelters, many of the plants being idle a considerable portion of the time, which reduced the consumption of natural gas. This reduction was offset in a way by new smelting plants built at Bartlesville and Coffeyville. Most of the cement plants, however, were in operation practically all the time, especially throughout the first half of the year, and consumed more gas than the cement industry consumed in 1907.

Three new plants were added to the list of consumers, one at Fredonia, Kan., which started late in 1907; one at Dewey, Okla., which began operations in the spring of 1908; and one at Chanute, Kan., which began during the latter part of the summer of 1908. With these additions it is evident that the total gas consumed by cement plants was fully equal and probably greater than that in 1907. The glass plants, brick plants and other factories have remained about as they were and their consumption of gas is, therefore, practically the same as in 1907.

RATES.

The rate at which natural gas is sold is almost uniformly 25c. per 1000 cu.ft. for domestic consumption, with a penalty attached if payment is not made by the 10th of each month. This is the price throughout practically the entire extent of the Kansas Natural Gas Company's pipe line service. In a few places a rate of 30c. is made. The Wichita Gas Company likewise charges 25c. in most places, but in the western part of its territory the rate is 30c. Each pipe line makes a great reduction for factories, the rate of 10c. per thousand being most common.

One or the other of these companies has bought out the local company in almost every town and village in the gas region, so that at the present time citizens of Topeka, Lawrence, Leavenworth, etc. obtain gas as readily and at the same rates as do the little villages in the heart of the field.

OKLAHOMA

In Oklahoma conditions are different. The rulings of the secretary of the interior on leased Indian land and the enforcement of the new law in the State prohibiting the piping of gas out of the State, thus far has prevented any considerable amount of gas being taken outside Oklahoma. Rumors are current that in at least one instance the law is evaded, and that a secret pipe line crosses the State boundary, but such rumors lack public confirmation.

One of the results of the enforcement of the State law and the rulings of the secretary of the interior is that no strong company has yet laid extensive pipe lines anywhere in the State for the purpose of supplying gas to the market. Each town in a measure, therefore, has its own pipe line, and obtains its supply from nearby pools. Very recently the Henry Oil and Gas Company arranged to build a 12-in. pipe line from the Hogshooter district into Bartlesville, a distance of from 12 to 15 miles. This has become desirable on account of the rapid growth of Bartlesville, particularly in the manufacturing plants established. Likewise, Tulsa is preparing to increase its gas supply by laying a large pipe line from the strong gas wells in the vicinity of Collinsville, a distance of about 20 miles.

Rates paid by consumers of gas in Oklahoma differ greatly in different places, not only for factory purposes, but for domestic purposes as well. A number of the communities are supplied by the old fashioned flat rates at from 5 to 10c. a gas jet per month for lighting purposes, and from \$1 to \$2.50.00 stoves per month for heating purposes. Elsewhere, but not very commonly, meter rates are established.

For manufacturing purposes gas is still offered at very low rates at a number of different places. Bartlesville, for example, immediately upon completion of arrangements to bring gas from the Hogshooter district, published far and wide that it would supply factories using large quantities of gas at the rate of 2½c. per 1000 cu.ft. for a number of years with an increase to 3c. later, which price was to rule throughout the life of the gasfields. Such offers are made in good faith and are used by different cities as inducements to draw factories.

GAS DEVELOPMENT IN KANSAS AND OKLAHOMA

Little attempt was made to obtain gas

in Oklahoma during the year, such wells as were obtained being incidental to oil developments. The only important exception to this statement lies with the Kansas Natural Company which did some drilling in Oklahoma expressly to develop gas. The result is that no new gasfield appeared, but here and there throughout the entire district frequently while drilling for oil good gas wells were obtained. In this way the supply was increased faster than the consumption; so that at the end of 1908 the portion of the Mid-continental field lying in Oklahoma is capable of producing a larger supply of gas than ever before.

In Kansas matters are different. Practically in every place where there was much hope for obtaining gas, drilling was prosecuted with zeal. The new field to the southwest of Chanute has been pretty well circumscribed on three sides, and a large amount of gas was obtained by various private individuals and small companies. The Kansas Natural Company also was alert and got hold of some exceedingly valuable holdings.

To the northeast of Chanute, and farther north by way of Humboldt toward Iola many wells were drilled, the great majority of which were successful, some of them developing from 10,000,000 to 15,000,000 cu. ft. per well. In the vicinity of Altoona also some excellent gas wells were obtained by the Altoona Portland Cement Company and private individuals. It is claimed by the cement company that it has one well with a capacity of 20,000,000 cu. ft. per day. Its territory virtually, however, is a southern extension of the pool southwest of Chanute already mentioned.

Farther north, in the vicinity of Colony, a small field of shallow gas was opened up with eight or nine wells ranging from 750,000 to 1,500,000 each. This, by the way, is an interesting locality, particularly on account of its non-productiveness. Colony is situated on the very summit of the most pronounced anticlinal ridge in the entire Kansas gasfield, and yet every deep well drilled in that vicinity has been a failure. The shallow field just mentioned lies east of town from two to three miles, and forms a narrow band trending a little northeast and southwest. The wells here are from 500 to 600 ft. deep, while the horizon supplying gas at Iola and elsewhere so abundantly in the State would be found at from 900 to 1000 feet.

The small gasfield developed more than a year ago in the vicinity of Rantoul near Ottawa is about the same as it was then, and in many respects is about like the Colony pool just mentioned. Here also may be named the Bonner Springs, and the Fudora pool, each of which furnishes a small amount of gas,

but neither of which thus far has been able to supply large quantities. The development during the past year lends but little encouragement to hope for great production from any of those light fields.

Farther west in the vicinity of Elmdale, Chase county, a small gasfield was developed more than a year ago, which remains about the same as it was when first developed. To the south and southwest from this place a number of small wells were found, particularly in the vicinity of Augusta and Arkansas City. It is to be hoped that future prospecting may increase the supply. Likewise, a little northeast of Elmdale in the same range 12 or 14 miles southwest of Council Grove light wells were found, but none of any particular promise for a strong gasfield.

The Appalachian Oilfield

BY HAROLD C. GEORGE*

The total production of petroleum in the Appalachian or the high-grade oilfields has been steadily declining for years. In 1908 there was a further decrease in the production, for the total production of petroleum in the Appalachian field for 1908 was 24,240,000 bbl., as compared with 25,500,000 bbl. in 1907., 27,345,000 bbl. in 1906 and 28,324,324 bbl. in 1905.

In addition to the natural decrease in production in the Allegheny field of New York State and practically all of the oilfields of Pennsylvania developments and operations have been retarded for several months by the drought and the resulting lack of water. Large numbers of pumping wells have stood idle for the past three or four months and consequently where such conditions existed no new wells were drilled.

It is only by the successful drilling operations in southeastern Ohio and West Virginia that the decrease in petroleum production in the Appalachian field has been gradual and slight rather than rapid and great.

West Virginia is the only district in the Appalachian field that holds out any great possibilities of increasing the supply of high-grade petroleum, for in the southwestern part of that State there is a large unprospected area. This region is now attracting the attention of prospectors. In both Jackson and Lincoln counties some prospecting was done during 1908, but as yet no large wells have been drilled. In Lincoln county nine wells were completed during April and May. These wells averaged 30 bbl. a day. In November twelve wells were completed which averaged 35 bbl. a day. Brooke county continues to lead all other districts in "gushers." The Follansbee pool in Brooke county and the

*Director of the Wisconsin State Mining Trade School, Platteville, Wis.

Holidays Cove pool in Hancock county attracted much attention during 1908, but it is generally believed that these fields are now on the decline. This section of the State had remained unprospected and undeveloped for years, but finally, after much drilling, oil was discovered in that section of West Virginia which lies across the Ohio river from Stenbenville, Ohio. Hancock county has long been noted for its large oil pools, but it is only recently that Brooke county has become a factor in the petroleum production of West Virginia. In Roane county operations continue most active and with profitable results. The best wells are found in the "Big Injun" sand.

In Kentucky and West Virginia weather conditions during October and November were very favorable for construction work in those sections of these States which are almost inaccessible in bad weather. Operators seized this opportunity to move in a large amount of material preparatory to drilling operations this winter.

The operations in southeastern Ohio have attracted some attention owing to the development of the Mingo pool, but like the Follanshee pool across the Ohio river in Brooke county, West Virginia, of which this pool is a part, the Mingo field also is on a decline.

All recent additions to the areas producing oil of Pennsylvania grade have been too small to have more than a temporary effect in checking the waning production. There was no change in the price of the high-grade petroleum during 1908. The price during 1908 staid at \$1.78 per barrel throughout the year; in 1907

The Adirondack Graphite Industry

By D. H. NEWLAND*

The Adirondack mines contributed the usual quota of crystalline graphite in 1908. For several years the production has averaged about 3,000,000 lb. annually, nearly all from the American mine at Graphite, Warren county. The success obtained in the operation of this mine by the Joseph Dixon Crucible Company has furnished an incentive to a great deal of exploration along the eastern border of the Adirondacks, which has demonstrated the widespread occurrence of the Pre-Cambrian graphite quartzites in that section, though workable deposits seem to be sufficiently uncommon. Besides the actual content in graphite, the size of the flake and freedom from other scaly minerals like mica are factors of prime importance in determining the value of a deposit.

The Crown Point Graphite Company and the Glens Falls Graphite Company were active during a part of 1908. The

The Lima Oilfield

By HAROLD C. GEORGE*

The oilfield of northwestern Ohio and northeastern Indiana known as the Lima oilfield has shown a falling off in petroleum production. The total production in 1908 was 7,287,000 bbl., as compared with 8,030,000 bbl. in 1907.

A large number of wells were abandoned in this field in 1908 and the production was maintained only by the increased activity in operation due to the higher market price prevailing in 1908 than in 1907. The average price paid for North Lima was \$1.03 per barrel as compared with \$0.93½ in 1907, and for South Lima \$0.98, as compared with 0.88½ in 1907.

There was a much smaller percentage of dry holes drilled in northwestern Ohio in 1908 than in 1907, as shown in the accompanying table, which gives the production of only those wells that were drilled during the year referred to.

*Director of the Wisconsin State Mining Trade School, Platteville, Wis.

WELLS DRILLED IN THE LIMA OILFIELD IN 1907 AND 1908.

the average price was \$1.74 per barrel. The accompanying table gives statistics regarding the production of oil wells drilled in the Appalachian field during 1907 and 1908.

In hydraulic sluicing operations in Victoria, Australia, according to D. B. Sellers, in the report for 1907 of the Secretary for Mines, the only improvement during the year was the introduction at the Creswick Black Lead and the Portuguese Flat hydraulic mines of high-lift centrifugal pumps coupled in series so as to give the pressure necessary for hydraulicking the gravel.

former company opened a deposit near Eagle lake, about 10 miles from Crown Point, Essex county, where it has erected a new mill with a capacity of 75 tons of rock a day. The crude graphite from this mill is refined and finished at a second mill situated at Crown Point Center. The mines and mills of the Glens Falls Graphite Company are near Conklingville, 8 miles west of Hadley, Saratoga county.

Some development work has been done during the year on a graphite-bearing quartzite just north of Saratoga Springs.

*Assistant State Geologist, Albany, N. Y.

Cadmium

This metal continues to be produced in the United States by but one concern, viz., the Grasselli Chemical Company, of Cleveland, Ohio. The production in 1908 was about 10,000 lb. At the beginning of the year the price was \$1.25 per lb. Later it was reduced to 75c. At the end it was 80c. These prices are for round lots. The production in Upper Silesia in the first half of 1908 was 35,000 lb., against 36,500 in the corresponding period of 1907.

Wolframite in India

Wolframite was discovered in 1908 at Agargão, seven miles southeast of Mamda, which is 20 miles east of Nāgpur on the main road from Nāgpur to Raipur. The ore is found in quartz veins intercalated in mica schist. The grade of the ore is good and the deposits are believed to be commercially workable. The discovery was made by J. Kellerschön, of Nāgpur, agent in India for the Carnegie Steel Company.

Mining in the United States During 1908

History of the Year in Various Camps of California, Colorado, Nevada, Montana, Utah, South Dakota, New Mexico and Other States

REVIEWS OF PROGRESS

The mining industry in the United States in 1908 was more or less under a cloud, as appears from the following reviews, although in the second half of the year, and particularly in the last quarter there was an improvement in sentiment. Yet after all, 1908 was not a very bad year. The production of copper and gold increased, while the outputs of the other metals were not very much smaller than in 1907, except in the cases of iron and a few of the minor metals. The average prices for the year do not compare unfavorably with the averages for the last 10 years. Why, then, was there so much complaint? Chiefly because the abnormal prices of 1906-7 stimulated the operation of many mines which ought not to have been opened.

Alaska

Members of the U. S. Geological Survey who have recently returned from Alaska report no great advance in the mining industry in the southeastern part of the Territory, although at some of the mines in the Juneau district—the Treadwell group, the Perseverance, and the Eagle River mines—substantial progress was made and extensive mining and water-power projects were undertaken, which promise well for 1909. The following article is compiled from recent reports by the U. S. Geological Survey.

JUNEAU DISTRICT

At the Treadwell mine developments have been pushed on the 1450-ft. level, which is to be used as a base for deeper explorations, and to this level the Seven Hundred Foot and Mexican mine shafts will be extended. At the Ready Bullion mine explorations are being made on the 1500-ft. level. The stamp mills were in continuous operation throughout the year, and the gold production will be about the same as in 1907. The use of oil as a substitute for coal for all purposes at these mines has reduced the fuel expense considerably, and additional water power has been provided by the building of dams on Ready Bullion and Fish creeks. Work on a project to obtain power from Turner lake, on the east side of Taku inlet, 18 miles from Treadwell, is being advanced. This project will necessitate the transmission of power across Taku inlet, a distance of 2½ miles.

At the Perseverance mine the lode de-

posit is now opened at the tunnel level for 1500 ft. in length and 60 to 100 ft. in width. The 100-stamp mill was in operation from June until November. Mining operations were in progress at the Alaska-Juneau mine from the last of June until the middle of October, and the 30-stamp mill was in continuous operation during that period. At the Eagle River mine developments were advanced, and the quartz veins which are displaced by faults, causing much difficulty in their exploration, have been discovered further in the mountain on the various tunnel levels. The 20-stamp mill on the property was supplied with ore obtained principally from the upper tunnel levels. Encouraging results are reported from the Yankee Basin prospects and from other properties within the Juneau gold belt, and also from the De Groff and Mills properties to the north of Sitka.

KETCHIKAN DISTRICT

The copper mines in the Ketchikan district suffered a considerable setback early in 1908 because of the decrease in the price for that metal, and except at the Jumbo mine operations were suspended during the winter. The Mount Andrew and Rush & Brown mines were idle throughout 1908; at the Mamie and Stevenson mines activities were renewed in August, and a relatively large amount of ore was mined, which was treated at the Hadley smelter. Explorations at these mines are to be advanced during the winter months, though the smelter suspended operations in November and no ore will be shipped. The largest production and most extensive developments during 1908 were made at the Jumbo mine, near Sulzer. The operations on this property were confined to the sulphide deposits at the head of Jumbo Basin, and only small developments took place on the copper-bearing magnetite deposits on the north side of that basin. The Niblick mine was operated from Apr. 15 to Oct. 30, during which period the shaft was sunk to a depth of 360 ft. and developments were extended on the 300-ft. level, where two orchobies were opened. Raises were made in these orchobies to connect with the 225-ft. level, and most of the ore thus developed was mined. At the It mine, on Kasaa Peninsula, mining operations were begun by the It Mining Company early in the spring, and a body of high-grade copper ore was developed.

A tramway one mile long was built to tide water, a wharf was erected, and ore shipments were begun in the first part of October.

The copper production of southeastern Alaska for 1908 will be less than that for 1907, but the average content of copper per ton of ore mined will be somewhat greater.

At the Calder Bay marble quarry near Shakan and at the gypsum mine on Chichagof Island work was in progress throughout 1908, and a large production is reported from each locality.

YUKON VALLEY

Three new localities for placer gold in the lower central part of the Yukon valley, brought to the public notice within the last two years, are of particular interest because they show that the gold-bearing formations of the valley are of much wider extent than has generally been supposed.

INNOKO DISTRICT

Since the discovery of placer gold, in 1906, on some of the headwater tributaries of Innoko river, that part of Alaska has received more attention from prospectors looking for new fields than any other district in the Yukon valley. The Innoko, the lowest noteworthy tributary of the Yukon entering from the left, is about 500 miles long and has been the principal route to and from the diggings on its headwaters. During 1906 small stern-wheel steamboats ran up the river to Dichkakak, about 250 miles from Anvik, on the Yukon. From Dichkakak it is 190 miles farther by the river to Ophir, the principal settlement at the diggings, and this distance is traveled in poing boats that will hold about one ton of freight. The most serious drawback to prospecting in the Innoko country is the difficulty and cost of getting supplies to a central distributing point convenient to the creeks on which pay gravel has been discovered. So far most of the provisions have been shipped into the district from Fairbanks, and by the time the freight is delivered at the town of Ophir the transportation cost has reached \$500 a ton.

The Innoko country has been staked in a wholesale manner, about 1200 locations being on record. Of this number only about 25 claims were worked during the summer of 1908; practically all of these were on Ganes, Little and Ophir creeks.

About 150 persons are now wintering in the Innoko district.

GOLD HILL DISTRICT.

The name Gold Hill is applied to an area in the central Yukon valley, about 25 miles below the mouth of Tanana river, that lies along the north side of the Yukon and extends westward from the western slopes of the valley of Tozitna river to the higher mountains north of the United States telegraph station called Birches. Roughly, the district embraces an area extending 30 miles east and west and 20 miles north and south, covering about 600 square miles. Most of this area consists of mountains that form a divide

on these streams has been located for placer mining. The locators are mostly association groups that enable a few men actually present on the ground presumably provided with powers of attorney from a number of absent persons, to tie up completely many thousands of acres of alluvial deposits bearing placer gold. The result of this practice is that many intending workers are unable to acquire ground rights and the healthy growth of the placer-mining industry is being retarded in a discouraging manner.

Open-cut ground-slucing operations have been begun at several localities in the Gold Hill area, but owing to the scarcity of water, due to the unusual

ft. high. This district received considerable attention from prospectors in the winter of 1907-8. Large tracts were located as placer-mining ground on Ruby, Melozi, Big, Main, Boston, Bonanza, Beaver and Dome creeks and their tributaries. A number of holes were sunk to bed rock during the winter, and prospects of gold are reported to have been found at several places. Discovery claim, on Ruby Creek, was the only property actively worked in July, 1908.

TIN DEPOSITS

Stream tin was discovered in the York region of Seward Peninsula during the fall of 1900 as a heavy and objectionable

SOUTHERN COPPER AREA OF ALASKA
(From map of U. S. Geological Survey)

extending east and west about midway between the main courses of the Yukon and the head-waters of the Melozitna. This divide separates the region into two areas that are drained to the north and south by creeks of moderate length and volume.

The principal southward-flowing creeks, named from east to west as they join the Yukon, are Grant, Illinois, and Mason and their tributaries; those flowing northward into the Melozitna, named in the same order, are Moran, Eureka, Hudson, Langford, and Tiffany creeks and their tributaries. It is in the gravel deposits of these creeks that the placer gold is found. Practically all the alluvial ground

dryness of the summer of 1908, there has been thus far very little production of gold.

RUBY CREEK DISTRICT

The area known as the Ruby Creek district—from the name of the small stream on which gold was first discovered in the area—lies on the south bank of the Yukon, directly south and opposite the mouth of Melozitna river, about 175 miles below Tanana, or 110 miles above Nulato. For a distance of 10 miles along the south bank of the Yukon the Ruby Creek country presents rolling hills from 400 to 500 ft. high that overlook the river with bluffs 200 to 300

constituent which accumulated in the sluice boxes of the placer-gold prospectors. A. H. Brooks, of the U. S. Geological Survey, who was engaged in a hasty reconnaissance of the region, brought some of this material back to Washington, where it was identified as cassiterite.

Developments in this region have been sufficient to demonstrate, at least, that the granite-limestone contacts are not favorable places to hunt for commercial bodies of cassiterite ore. Quartz porphyry dikes, locally known as lodes, or even as quartz veins, have been prospected to some extent, owing to the fact that the original discovery of lode tin in Alaska was made on a mineralized or altered dike of this

character. The value of any such dike depends on the number of cassiterite stringers which it contains and the closeness with which they are spaced. Of itself a quartz porphyry dike has no value. The unwelcome fact should be speedily realized that few of these dikes hold out any inducements whatever as prospective tin producers.

Most of the developments throughout the region are still in the prospecting stage, and many of the open cuts have not uncovered solid bed rock. No tonnage of

mineralization is not limited to the region at the head of Buck creek, but is more widely spread throughout the slate belt. It is probable that a great granite mass, of which the stocks at Brooks mountain, Tin creek and Cape mountain are protruding bosses, underlies the entire York region.

COPPER RIVER REGION

Active prospecting was carried on in 1908 on the head of Nabesna river, on Cross creek (or Copper creek, as it is

development work is not yet sufficiently advanced to give an idea of their extent.

The copper minerals on Copper creek are found in lavas and consist chiefly of chalcopyrite and chalcocite, but include also cuprite and native copper. The copper deposits of White river consist of copper sulphides and native copper in lava flows. Native copper is found in greatest amount near the boundary line. This region gives some promise to the prospector for gold-lode deposits, and development work on a vein of argentifer-

MAP OF MOUNT WRANGELL DISTRICT, ALASKA, SHOWING POSITION OF THE COPPER BELT AND ROUTE OF THE PROPOSED RAILROAD (Based on map of U. S. Geological Survey)

tin-bearing rock, except at one place on Lost river, has yet been blocked out. Small holes in the ground, which give no clue to either dip, strike, or persistence of the ore rock, are held at enormous figures. The great need of the country is less desultory prospecting. The slate area deserves more careful examination, as it is possible that valuable quartz veins may exist within its confines. The distribution of stream tin in Anikvik river and its tributaries proves that the stanniferous

now called), and on White river. The White River prospects are situated in two areas—one at the head of the river, in the vicinity of Skolai glacier, the other near the international boundary line, partly, it is supposed, in Yukon Territory. Prospecting in the region northeast of the Wrangell mountains is restricted almost wholly to the search for copper. The best known copper prospects on Nabesna river are near the foot of Nabesna glacier, in the vicinity of Orange Hill, but

ous galena associated with sphalerite has been begun.

Prospecting in Chitina valley was discouraged during 1908 by the low price of copper and the consequent difficulty of obtaining financial backing, but some effective development work was done. At the Bonanza mine the season was spent in erecting a sawmill, ore bunkers, buildings for various purposes, and an aerial tram from the mine to the camp.

Development work was done on the ex-

tension of the Bonanza in the upper part of McCarthy creek valley by the owners of the Mother Lode claim and by the Houghton Alaska Exploration Company. The largest operations in the remainder of the field were those of the Alaska Consolidated Copper Company on Nugget creek, the Hubbard Elliott Copper Mines Development Company on Elliott creek, and the Great Northern Development and Alaska Kotsina Copper companies on Kotsina river.

Placer mining was active on Dan and Chititu creeks during the summer. The two hydraulic plants on Chititu creek continued operations in 1908 but experienced some difficulty in procuring labor, a difficulty encountered at the Bonanza mine also.

Probably the most important work affecting the future of the Copper River region is the construction of the railroad from Cordova to the interior. During 1908 more than 50 miles of track were laid, bringing the road to the bridge over Copper river between Childs glacier and the lake in front of Miles glacier. This road will establish communication with steamboats on the river above Abercrombie rapids and it will be possible to carry freight from the coast at Cordova to Copper Center on Copper river or to the mouth of Lakina or Nizina river on the Chitina. Construction work is also being pushed on a short piece of road connecting the Bonanza mine with Chitina river, and its completion will make it possible to carry supplies to the mine or to ship ore to the coast before the whole of the railroad up the river is completed. A branch line to the Bering river coalfields is also under way.

Arizona

BY WILLIAM P. BLAKE*

The cloud of industrial depression which hung over the country for the greater part of the year 1908 was not without a serious depressing effect upon the mining enterprises of the Southwest. With the exception of the well established copper, gold and silver mines, the mining prospects generally were closed down. But with the brightening skies of November and December there was renewed activity giving promise of prosperity for the year 1909.

GOLD

Gold, the second in value of Arizona's mineral productions, was officially reported as amounting to \$2,617,312 in value in 1907 and is believed to have equaled, but not to have exceeded that figure for 1908.

One mine, at least, was added to the list

*Territorial geologist, Tucson, Ariz.

of producers, the Mohawk, in the Old Hat district, Pinal county, near Schultz. It ranked high as a producer for several years, but until 1907 remained closed down for a decade or more. Under the management of William Roberts, it has been reopened. The shaft was sunk from the 300- to the 500-ft. level. Drifting on the contact between granite and an eruptive rock opened up new bodies of oxidized free-milling ore. The mill of 30 stamps was started in September, and has since been satisfactorily producing gold bullion. The tailings do not run high enough to justify cyaniding. Water is not expected until a depth of 725 ft. is reached, this being about the level at which it stands in the neighboring mine, known as the Mammoth, which is idle. Like the Mammoth ore, there is a notable amount of wulfenite in it, but not exceeding 1.4 per cent., insufficient to pay for the extraction by concentration as was adopted with the tailings at the Mammoth mill on the San Pedro.

In the extreme southwest of the territory the Fortuna has ceased to be a notable producer. In the Quijotoa region, the Weldon Gold and Copper Company, under the management of Director Fitch, continued operations through the year. About 300 ft. of driving and sinking was added and rich gold and silver ore was opened up. The capacity of the mill was increased by new stamps and a cyaniding plant. The copper-bearing part of the property was reached by a shaft penetrating the ore 300 ft. below the outcrop of gossan. Shipments of oxidized ores averaged from 22 to 30 per cent. of copper. A second shaft 1000 ft. west reached a depth of 330 ft. on the footwall with the expectation of striking a body of sulphide ore.

The mines of the Congress and other gold properties of the Piedmont region of the Bradshaw mountains continued in operation. The Octave mill was started late in the year and resumed its additions to the bullion product of the territory.

Near Prescott, Yavapai county, the Bullwhacker gold-quartz mine has been worked since January, 1907. The quartz carrying coarse gold of high grade in 1908 was worked at the Oriental mill, Poland.

The Arizona Copper-Gold Mines property was worked up to Sept. 20, opening up reserves of ore ready for the crushing machinery to be added early in 1909. In northern Pinal county development work on the gold-bearing veins in the Saddle Mountain mining district, south of the Gila river, was resumed in the latter part of the year, particularly upon the mines of the Ash Creek Company. There are now 600 ft. of workings, with the shaft 100 ft. below the main tunnel level. The vein may be said to be double, being formed on both sides of an intrusive porphyritic dike. A crosscut shows the

south side vein to be 20 in. wide, assaying from 5 to 20 per cent. copper and from \$20 to \$70 in value for gold. The north vein is about 4 ft. wide and assays 4 per cent. copper.

There are several groups of similar veins all traversing andesitic rock, giving by their weathering and erosion placers of considerable value. The Ash Creek Company's ground gives access to these veins by a tunnel at a low level. A concentrating mill is needed, and projected at the river, by which rich auriferous concentrates could be taken from the mines of the district.

In the Bunker Hill district, east of Mammoth, prospecting by the Calumet & Arizona company of Bisbee, during the year, was so satisfactory that there are now three different companies and nearly 100 men at work there. The district within which there are good evidences of copper and gold ore is described as about five miles wide and 12 miles long. Machinery is on the way for the erection of a 200-ton concentrator. In Mohave county there are many producing gold properties from which no reports have been received.

Near Kingman the Gold Roads is operated by Porcy & Bailey, and the Blue Ridge by men from Pasadena, California.

The Gold Crown group, also near Kingman, in the Union Pass section, is reported to have developed promising ore-bodies, so also the Tyro groups.

At Cerbat, the Golden Gem reached in its shaft a depth of 500 ft. and cut a body of high-grade gold ore according to a late report.

In northern Yuma county the Signal mine, 20 miles north of Bouse, was opened by a shaft to a depth of 300 ft. and a large body of low-grade auriferous copper ore was reached by a crosscut on the 200-ft. level.

At Salome, Yuma county, north of the Harqua Hala mountains, the closing of the year witnessed increasing activity, and the development of the Ullimatum copper flat and the Cahalla properties in the limestone belt of Tank Pass.

At the Harqua Hala the efforts to work the fillings of the old stopes ceased and attention is now given to unwatering and sinking for new orebodies below the old works. This mine is said to have produced upward of \$7,000,000 in value above the 300-ft. level. The reopening of the old Vulture mine is reported.

SILVER

The production of this metal, third in value of Arizona's minerals, may be estimated at 2,000,000 oz. fine for 1908, or somewhat less than the figures given officially for the production in 1907 (2,511,897 oz.). The Territory was formerly celebrated as the source of many ponderous masses of nearly pure silver

from the gravelly placer deposits near Globe.

During the year 1908 the Old Stone-wall Jackson mine, supposed to be the source of much of the placer silver, was reopened and at the depth of 280 ft. a rich vein of silver is reported to have been found. There were also efforts looking toward a resuscitation of the Silver King mine in Pinal county, but active work has not resulted.

Most of the silver production is derived from the smelting of argentiferous lead ore and from the silver-bearing gray-copper ores.

ARGENTIFEROUS LEAD

The silver-lead mines of Santa Cruz county remained practically as at the close of the year 1907. The Hardshell and the Flux mines near Patagonia, Santa Cruz county, noted for their large bodies of argentiferous lead ore and carbonates suitable for smelting operations, which were under bond in 1907-1908, are still under bond. The deepest workings on the Hardshell are 500 ft., by an incline shaft. It is claimed that there are fully 100,000 tons of ore that will assay 10 per cent. lead and 10 oz. silver per ton. In crosscutting from the 500-ft. station to the ledge a large flow of water was encountered which stopped further mining operations for a time. The deepest shaft on the Flux was carried down to the 260-ft. level, opening up, by estimate of owners, 50,000 tons of ore assaying 12 per cent. lead and 6 to 8 oz. silver to the ton. The World's Fair mine is closed, and was for most of the year 1908.

During the year operations at the Salero mines were confined to the extension eastward of the lower drift on the Eureka Mabel, and westward on the same lode, and to surface surveys for patenting the Eureka and other claims beyond. Work was delayed somewhat by the uncertainty of ownership entailed by the claimants of the Baca Grant Float No. 4 and the consideration of the claims by the department of the interior. The full investigation having shown conclusively that a large part of the region covered by this Baca location was well and publicly known by publications to be mineral land prior to the location, the claim, after repeated hearings, was dismissed, and it no longer blocks mining or farming locations.

The "Constitution" or Darwin lode at Happy Camp, on the south side of Salero mountain, was under exploration during the year by sinking a vertical two-compartment shaft, which, at the close of the year, reached a depth of 300 ft. It is proposed to crosscut to the ledge at the 500- or 600-ft. level, to intersect the supposed prolongation of the shoot, or chimney, of high-grade silver-copper ore mined out above the 150-ft. level.

The Alta mine opened on a lode of argentiferous gray-copper and galena ore, similar to that of the Eureka, remained closed during the year, the transportation facilities not being favorable to the shipment of the ores to smelters.

The Tia Juana group of claims on the great quartz ledge carrying iron pyrites, chalcocypite, galena, tetrahedrite and blende, which crosses the diorite ridges at the head of Josephine cañon, in Santa Rita mountains, was surveyed and patented, and will be worked when railway communication is established along the Santa Cruz valley, by which the ores and concentrates may find an outlet. The Mowry silver-lead mine, south of Patagonia, was not actively worked during 1908. The smelter remained closed down, but some exploratory drifts were run in the mine.

The Vekal silver-lead mines, 35 miles southwest of Casa Grande station, on the Southern Pacific railway, which were large producers of silver-lead ore in the years from 1885 to 1904, were reopened and the concentrating mill of 10 stamps with Wilfley tables is in operation. One shipment of a carload of concentrates was made. A double-compartment shaft was sunk to the depth of 380 ft. so as to reach and open up new orebodies at lower levels. The old workings, said to measure more than five miles in total length, are found to contain a large amount of low-grade ore suitable for profitable concentration. The Commonwealth, also known as the Pearce mine, in Cochise county, continued in successful operation under lease to Swatling & Smith. There were 34,763 tons of ore taken from the mine, crushed dry and cyanided direct. These ores were passed through a Blake crusher and four sets of Chalmers-Williams rolls, one set 15x36 in., two sets 15x30 in., and one set, finishing rolls, 10x30 in. Two additional sets were recently added to increase the capacity and to crush through 10-mesh instead of 8-mesh screens. With this plant the capacity is 150 tons in two shifts of eight hours each. By pan-amalgamation 28,912 tons of medium grade ore were treated. This was crushed by stamps. For a part of the year 30 stamps were used, but 10 stamps were dismantled in June to install more rolls, and since then only 20 stamps were used, averaging two tons to the stamp. The tailings from the pan-amalgamation process (11,040 tons) were treated by cyanide. The figures of production and treatment pertain to the months of 1908 up to November 1.

The lessees state that in 1908 they have mined and milled more ore than at any time during the life of their lease, which dates back to May, 1905. They expect to treat 200 tons daily during 1909; 150 tons of this will not average more than 5½ oz. silver and 8oc. to \$1 in gold.

The mines of the Tombstone camp were continuously operated by the Tombstone Consolidated Mining Company, and more ore has been extracted and shipped from lower levels than ever before. Water at the rate of 5000 gal. per minute is pumped from the 1000-ft. level.

NEW RAILWAY FACILITIES

The construction of the Arizona & California railway across northern Yuma county from a point between Congress and Wickenburg westward to and beyond Parker on the Colorado, gave access to the rich mineral region hitherto remote and neglected. It passes by the Harqua Hala mountains, toward Quartzite, then winds northwest by the town of Bouse toward the Bill Williams Fork region and gives an outlet to the mines of the Santa Maria mining district and about Parker on the Colorado river. The early completion of this road drew renewed attention to the mining districts along its route, and active prospecting in 1908 resulted in the addition of many promising properties, bearing copper, gold and silver.

Colorado

BY GEORGE E. COLLINS*

Mining in Colorado during 1908 was on the whole in a distinctively depressed condition. The low prices for all the commercial metals resulted in a considerable lessening of output. With the exception of Cripple Creek and Telluride, both of which are essentially gold-producing camps, every district throughout the State was materially affected not only by the low metal prices, but also by the fact that the financial conditions in the Eastern States necessitated the postponement of new outlay both for equipment and for prospecting. The tonnage of ore received at the various plants of the American Smelting and Refining Company, which may be taken as a fair index of the condition of the mining industry, outside of that from purely gold-producing mines, was about 550,000 tons as compared with 796,000 tons in 1907, a decrease of approximately 30 per cent. Owing to the lower prices received for the product, the falling-off in value was still more serious.

GOLD AND SILVER

CRIPPLE CREEK DISTRICT

A reduction in the costs of treatment at the custom chlorination plants was in force during the greater part of the year and resulted in an increased tonnage. This increase, however, was mainly in shipments of very low-grade material, so that the total output was of

*Mining engineer, 420 Boston building, Denver, Colo.

less value than has been generally supposed. The minimum price for freight and treatment was \$3.50 per ton; this rate enabled the shipment of great quantities of dump material. So far, however, as can be learned at the time of writing, the shipments of ore of the better grades were decidedly smaller than during 1907, and the value of the output correspondingly reduced.

The principal producing properties were the Portland, Elkton, Golden Cycle, Strong, and Cresson; an important output was maintained by leasers working in the El Paso. Of the outside leases, the most profitable and productive was probably that on the Lucky Gus Mine; the Dante leases hardly came up to what was expected.

The drainage tunnel has made good progress, the face being now in about 4500 ft. from the portal. The footage reported during the last few months of the year has been particularly gratifying. The new mill of Stratton's Independence was completed early in the year, but owing to a variety of causes, principally financial, it has not yet been in steady operation. It is understood that these difficulties have now been straightened out so the mill should add largely to the production next year. The future of Cripple Creek depends largely on the cheap treatment of the low-grade ores. Discoveries of high-grade orebodies seem to be fewer in number each year, and it is improbable that the existing rate of production can be maintained much longer from ore of the present grade; still, the completion of the drainage tunnel and the introduction of cheaper milling methods may result in maintaining Cripple Creek as the chief gold-producing district of Colorado for many years to come.

SAN JUAN COUNTRY

The Ouray district was comparatively inactive, with the exception of the great Camp Bird mine, which maintained a large production throughout the year. It is, however, generally understood that the orebodies in that mine are approaching exhaustion. At Telluride the Tom Boy, the Smuggler-Union and the Liberty Bell maintained the same output as for some years past, but the Smuggler-Union was considerably affected by the low price of silver. At Silverton, the Gold King was shut down for several months, on account of a disastrous fire. The Silver Lake was compelled to curtail its production on account of the low values of lead, silver and copper and at present the mine is being worked only by lessees.

CENTRAL DISTRICTS

Leadville and Aspen were both seriously affected by the drop in silver. Until the drop in silver, however, the Cresscentia and Reindeer shipped largely. A

considerable production of gold-bearing material was made from the territory contiguous to the Ilex properties. The Dinero tunnel was completed to the vein during the fall, and development work is now in progress. At Aspen the production, as to quantity, was not much less than in 1907. The Della S. and Durant shipped a large tonnage; in the latter case low-grade lead-silver ore, that was mined by lessees. The Percy LaSalle was shut down, but the Smuggler mill ran continuously throughout the year. At Creede also the tonnage handled was about the same as in 1907, but here again the low prices of metals must have seriously curtailed the profit margin.

NORTHERN COUNTIES

From Gilpin county the output was perhaps a little better than in 1907, but as a whole the district has been in a depressed condition. The opening-up of important orebodies in the Bobtail vein on the lowest level promises an increased production in 1909, while the resumption of work in the Newhouse tunnel is certain to lead to a revival in the district around Nevadaville. The Georgetown district was hard hit, on account of the low metal prices. Although the high-grade silver ores cannot fairly be described as approaching exhaustion, it is unfortunately true that the discoveries made of late years have been of small extent. The amount of development work done, however, is altogether inadequate, and is likely to remain so unless capital is invested from outside. An important orebody, the value in which is largely gold, has been opened up in the Capital tunnel, and a mill has been built at the entrance of the tunnel to handle this ore. At Idaho Springs, the Stanley and Lamartine mines have been producing very little ore. The Gem and Little Mattie mines, both operated on the leasing system, have been probably the largest contributors to the output. The Sun and Moon mine, on the boundary line between Gilpin and Clear Creek counties, has been opened up with a raise, from the level of the Newhouse tunnel, that connects with the lowest workings from surface. Several levels from this raise have been commenced in ore, and probably in 1909 this mine will be the largest producer in the district. The resumption of work in the heading of the Newhouse tunnel, which took place on Dec. 16, is likely to prove of great permanent importance to this district.

The well known Alice orebody, at the head of Fall river, is again being tested; the result of several careful mill-runs indicates that it is susceptible of profitable working on a large scale. There is very little of importance to report with reference to developments in Boulder and

Summit counties. The large dredging operations planned for the Breckenridge district have been delayed, as a result of the financial stringency in the East.

LEAD AND ZINC

LEADVILLE

The operations of the Western Mining Company at the Coronado and Penrose mines were suspended in December, 1907, as a result of the fall in metal prices, and the pumps were taken out. Work was, however, continued for several months thereafter by lessees, who continued shipping until the water drove them out. The Moyer and Tieson mines of the Iron-Silver Company have remained idle throughout the year. The Yak-Tunnel properties have, however, maintained a large output.

MINOR DISTRICTS

At Creede the output, as to quantity, has been fairly well maintained, but the fall in value has been seriously felt. In the San Juan, as indeed everywhere throughout Colorado, the mines producing lead and zinc depend mainly for their profit on the gold and silver in the ore, since the lead and zinc are in the nature of by-products, though often very important ones. The partial suspension of the Silver Lake mine has been already referred to; the Iowa mine, also near Silverton was disabled by a snow-slide during the winter, but has been reopened by a leasing company. On the whole, outside of Leadville, the output of these metals has been affected less than might have been expected; but, should a recovery in the value of silver be long delayed, it is probable that 1909 will witness a further falling off.

COPPER

The production of copper in Colorado is not of equal importance with that of the metals previously mentioned. It is, however, notable that the quantity, if not the value of the copper produced, has increased. This is due partly to shipments from the Leadville district, and partly to several discoveries in the San Juan; notably at the San Antonio mine in the Red Mountain district, and at the Frank Hough mine near the dividing line between Hinsdale and Ouray counties.

RARER METALS

TUNGSTEN

The demand for tungsten was very much lessened during 1908, largely because of depression in the steel industry, and the price was correspondingly reduced. For this reason the industry in Boulder county was inactive, and the value of the output for the year was probably less than \$100,000. Lately the demand seems to have revived somewhat, and mining and milling are being more ac-

tively carried on. An unusually snowy winter, however, will tend to retard production, even if the demand should be good. Nothing has been done toward the development of the sporadic occurrences of tungsten ore in the San Juan and other districts throughout the State.

VANADIUM AND URANIUM

The milling plant of the Vanadium Alloys Company at Newmire, near Telluride, was operated continuously during 1908. A new McDougall furnace is being installed, and the output will be largely increased.

The discovery of a body of pitchblende ore in the Belcher mine on Quartz hill in Gilpin county is reported. This mineral occurs in quite a number of veins including the Wood, Kirk and German, but the occurrence is pockety, as isolated lenses in gold-bearing fissure veins.

Montana

By H. K. WELCH*

Difficulties between the miners and operators about the wage scale, and the resulting strikes occurring during the last six months, had their effect upon the coal production of the State for the year 1908. At Roundup, in Yellowstone county, the Chicago, Milwaukee & St. Paul Railroad during the year developed some mines which will eventually become large producers. The Washoe Copper Company's mines at Bear Creek, Carbon county, were brought to a producing state and thoroughly modernized, although of late they have not produced to their full capacity, which is about 700 tons daily. At Red Lodge, in Carbon county, the Northwestern Improvement Company mines held first place in the State in the amount of production. Almost the entire output was used by the Northern Pacific Railway Company. At Chimney Rock some new properties of Evans & Anderson were opened up; they give every indication of becoming large producers. The mines of the Great Northern Railroad at Sand Coulee, in Cascade county, were in almost constant operation throughout the year.

COPPER

Copper is easily the first mineral in importance in the State, and Butte is the leading copper camp. While the low price of the metal, and severe floods interfering with transportation, tended to lessen the output, still little decrease will be shown from the output of 1907. In the Butte district the effects of the financial panic of 1907 kept the mines closed for the first two months of 1908, and they had barely got under way when the floods and the consequent damaging of the Boston & Montana smelter at Great Falls caused

a very material curtailment of the production from the Boston & Montana mines in and around Butte. The Anaconda company, with its High Ore, Never Sweat, Anaconda, Mountain Consolidated, St. Lawrence, Bell, Diamond, Buffalo, J. I. C., Modoc and Belmont mines, with the exception of the first two months of the year, worked almost continuously. The Anaconda and St. Lawrence mines were hampered to a certain extent because of the fires smouldering in the old stopes. The High Ore, with its depth of 2800 ft., is now the deepest mine in the camp. As a result of the deepening of the Belmont shaft so as to connect it with the lower levels of the Anaconda, nearly 400 ft. haul will be saved in hoisting the ore of the latter mine. The Butte Coalition Company accomplished a great deal during the year. At its Tramway mine a new gallows frame and hoisting engine were installed and new machine shops, carpenter shops, and office buildings were erected. Through the workings of the Tramway an enormous amount of development work was done in Minnie Healy ground on the 1400-, 1500- and 1600-ft. levels. Several connections were also made with the Rarus mine.

The Cora mine of the Coalition Company is worked through the Anaconda company's Diamond mine. As a whole the mines of the company are in much better shape than ever before, both for the production of a larger quantity of ore and for more economical mining. The Boston & Montana company operated during the year the Mountain View, Leonard, Pennsylvania, and East and West Colusa mines. At the West Colusa work was somewhat retarded by the fire which has been present in the mine for more than a year. At the Leonard a new shaft was sunk and the daily output of the mine for the last few months of the year was greater than ever before.

The Butte & Boston company operated almost continuously the Silver Bow, Berkeley, and East and West Greyrock mines. The Parrot company worked the Parrot and Little Mina mines. While the showing of the Parrot mine for the year was rather poor, in the Little Mina several bodies of good ore were opened up. The Trenton Mining Company, operating the Gagnon mine, was able to obtain better ore than at any time within the last few years.

The Original Consolidated Mining Company, in which W. A. Clark is the controlling factor, was able to work throughout the year unaffected by floods or the financial panic. The Original and West Stewart mines are the principal producers of this company, and the ore is treated in the Butte Reduction works, owned by the same men. The ore in these mines has improved with greater depth. W. A. Clark also operated the

Elm Orlu and Poser mines, which are situated in the North Butte district. The North Butte company during the year sank its shaft from the 1800- to the 2200-ft. level. On the 2000- and 2200-ft. levels crosscuts were driven to the veins, and they were found to be fully as good if not better than those on the 1600- and 1800-ft. levels. The mine averaged in production about 1400 to 1500 tons daily during the year, with about 900 men employed.

At the mine of the Pittsmtont company, formerly the Pittsburg & Montana company, the processes under experiment for treatment of ores proved to be a costly failure and were discarded by the new management, with Oscar Rohn in charge. Under Mr. Rohn's management the smelter was overhauled, a new 250-ton concentrator was built and the property was put on a paying basis.

The La France Copper Company operated the Lexington mine and did considerable work on the 800-, 1000- and 1400-ft. levels. Good bodies of copper ore were opened up and with further development the property may become a large producer.

The Davis-Daly company underwent a complete reorganization after the financial panic, but continued to operate all but a very short period of the time. At the Colorado shaft, where the work was carried on more extensively than elsewhere, the shaft was sunk from the 1000- to the 1500-ft. level. The property has a favorable location and has good chances to develop into a producer of merit.

The Butte & Superior company confined its operations to the Black Rock mine in the northern section of the Butte camp. The shaft was sunk from the 800- to the 1350-ft. level. The last place at which a crosscut was run to the vein was on the 1000-ft. level, which was found to contain a small percentage of copper.

The Tuolumne Company succeeded in developing a body of commercial ore and made large strides toward becoming a regular producer. The shaft was deepened about 400 ft. during the year and is now 1200 ft. deep. The latter part of the year work was begun installing an entire new surface plant.

At the mine of the Raven company development work progressed steadily under the direction of John Berkin. The shaft was sunk an additional 400 ft. during the year and is down about 1250 ft.

The Butte & Balaklava company continued development work on the claims in Meaderville without interruption and sank the shaft from the 500-ft. to the 1150-ft. mark. Four veins were cut on the 1000-ft. level, all showing commercial ore.

The Butte-Milwaukee company resumed operations late last summer; the principal work was confined to the 300-ft. level.

*Butte, Mont.

The Butte & London company worked but a few months in the year; when it ceased operations the shaft was down 1100 ft., and operations had cut several veins of commercial size and well mineralized. The company ran out of funds before it had an opportunity thoroughly to explore the property.

The Lewisohns sank shafts on the Granite Mountain and Flat Iron claims in the North Butte district, but discontinued the work a few months ago. Both shafts were more than 500 ft. in depth when sinking was discontinued.

In the Butte camp about 10,000 men were employed steadily and more than 16,000 tons of ore were mined and shipped daily in 1908. Of this amount the Amalgamated* mines contributed about 12,500 tons; the North Butte 1450; Clark properties 1100; Coalition 1100; Pittsment 350; and others 300 tons. The copper production for the year averaged 29,000,000 lb. per month, and for the district during the entire year the production was about 270,000,000 pounds.

In the Corbin district in Jefferson county the Boston & Corbin company's property reached a depth of 500 ft., and several bodies of commercial ore were opened up. Other properties upon which work was done are the Black Jack, Corbin-Wicks, Corbin Consolidated and Alta. The Montana Consolidated company's property near Basin was operated steadily. The formation in the Corbin district generally is very similar to that of Butte, the granite being coarse-grained and micaceous. The veins also resemble the Butte veins, with the exception that the sulphides are found nearer the surface.

At the property of the Monitor Mining Company in Missoula county, H. F. Samuels was in charge of the property and a rich mine was opened up. Several shipments of ore were made. The principal mineral in the ore is chalcopryite. In Meagher county the Copperopolis mine, owned by the Daly estate, was worked by leasers all year and several shipments of high-grade ore were made. The shaft is down 500 ft. The Silver Fissure Mining Company carried on operations on a small scale during the year at the property near Polaris in Beaverhead county.

ZINC

The principal zinc district in Montana lies in and around Butte. In fact, the La France Copper Company's Lexington mine produced a large quantity of zinc during the year. A mill was erected on the property for the separation of the zinc product, but it did not prove to be an unqualified success and has been closed for some time. On the upper levels of the Elm Orlu and Butte & Superior properties immense bodies of zinc were discovered in a search for copper. The Comet mine, near Basin, in Jefferson

county, produced considerable zinc and much experimenting was carried on all year for the separation of this product.

GOLD AND SILVER

From a mining standpoint in Montana, gold is secondary to copper. There are, however, several districts which operated continuously for gold during the year. In the Garnet district in Granite county the Mitchell & Mussighroad properties made several rich shipments. The Anderson & Magone properties in the same district were turned over to a new corporation, the Anderson & Magone Mining Company, which will carry on operations. In the Cable district, in Deer Lodge county, the Cable Consolidated Company operated practically all year with a small force of men. The operations were confined principally to development work.

At the Southern Cross mine operations were continued throughout the year and consisted principally of development work. A new mill was erected on the property. The Gold Coin mill and mine also ran for the last few months. At the properties of the Milwaukee Gold Extraction Company the work was uninterrupted. In the Radersburg district in Broadwater county the Keating mine made steady shipments to both the Pittsment and to the Washoe smelter.

In the Granite district in Granite county the Granite Bi-Metallic Company operated its properties in a small way under the management of John R. Lucas and several shipments were made to the East Helena smelter. In the Ruby district in Madison county, a new gold dredge was built, making three in all, and operations were carried on all year. In Silver Bow county the British-Butte company finished the construction of a Ridsdon gold dredge, but the machinery has not as yet been put in operation.

New Mexico

BY REINOLD V. SMITH*

Activity in the mineral industry of New Mexico during 1908 fell short of that of former years, but the Territory was by no means alone in this respect. The principal mineral product was coal, and the demoralized metal markets did not affect this branch of the industry seriously. In fact the conditions are in many ways better than ever before. Many business changes were brought about, but the development of the great dormant mineral resources did not stop with the shipments of ores.

Three new gold camps attracted wide attention, and one of them, Sylvanite, is

*Professor of mining engineering, School of Mines, Socorro, New Mexico.

destined to become a mineral section of great merit and importance. One other, Hachita, has been periodically discovered, under different names, since the advent of man to this southern section of the country; and since the placer gold there found is in what would be considered rich gravel in California, it is likely soon to be "discovered" by men who are able to unravel the problem of recovering gold from gravel worth from 13c. to a dollar and more per yard, but where water is hard to get. Much gold has in the past come from this section, but conditions have been so unfavorable that prospectors have sought other fields of opportunity where the washing of the gravel seemed to present fewer difficulties.

In Sylvanite the parent stock of much of this placer gold has undoubtedly been discovered. Though as yet the precious metal from Sylvanite has not been shipped in sufficient quantities to attract attention by reason of its money value, nevertheless the ores appear to be of a permanent character, of good grade, and of wide distribution. At the close of the year shipments were made regularly by wagon from several of the claims.

All of the producers of coal continued production throughout the year, and improved their plants more or less to meet an expected demand for the future. The agitation of new railroad enterprises brought to light many resources unknown to the general public. One railroad, the New Mexico Central, commenced grading and laying track. The feeling is abroad in the mining world that the market conditions which prevailed last year will speedily improve during this present year, and all are preparing for an active season of production during 1909.

During the year, coal, iron, gold, natural cement, copper, lead, silver, zinc, turquoise, meerschaum and vanadium were mined and shipped. Marble, and building stone of various qualities, were produced as usual for domestic use, and a little for transport. Systematic search for oil was carried on at several points, and salt was gathered on a small scale.

COAL

Prof. A. K. Adams, of the department of geology in the New Mexico School of Mines says regarding coal in the Territory: "The vast coalfields of New Mexico, about ten million acres, have scarcely been scratched, although the annual production is more than 2,500,000 tons."

Each of the coalfields has from two to six seams of workable coal, and in many cases the coal mined is more than 5 ft. thick, practically all of it being Cretaceous. Most of the coal (two-thirds of that now mined) comes from the northern part of the territory, near Raton, and it is in this region that most systematic and scientific mining operations are carried on. This coalfield is the southern extension of

the Trinidad field of Colorado and its coal produces excellent coke.

The greatest producer was the Phelps Dodge company of Arizona, which operates coal mines and coke ovens at Dawson. The Hagan coalfield, just north of Albuquerque was developed during the year, and plans are well under way for a branch railway to connect this district with the Santa Fe railroad, and thus to make the coal more marketable. The Cerillos district produced the only anthracite in the Territory; one seam of coal there is anthracized by a sheet of andesite near it. There were no special developments in this field, mining continuing as usual. At Carthage a short branch connects the Allaire mine with the railroad. The Western coalfields near Gallup were in active production all the year furnishing domestic and steam coal.

Surveys were made for a new railroad in the western part of the Territory; this will furnish transportation to the mines near Silver City, Cooney, and Mogollon, and also the large coalfields south and north of Gallup. If this line is completed it will open up a large area that has great mineral wealth but is as yet little known.

The Bernal mine at Carthage had a dust explosion early in January which killed 12 men, that being the only serious accident in the Territory this year.

IRON

Next to coal in importance stands copper, so far as present value is concerned. Potentially, however, the worth of iron is greater to the Territory. Up to the present time the Colorado Fuel and Iron Company has alone profited by the vast deposits of excellent iron that exist in the Territory. The properties of this company are situated in the Fierro district and at Hanover, about nine miles east from Silver City, in the southwestern part of the Territory, whence the ores are shipped over the line of the Atchison, Topeka & Santa Fe railway to Pueblo, Colo., for reduction.

At the beginning of the year the mines worked a full force of about 240 men and shipped about 500 tons a day. During the year production was reduced, but at the close of the year it was again increased, shipments being about 400 tons a day. The total product for the year was 94,000 tons.

Besides the deposits at Fierro many others of wide extent are known; for instance, those at the north end of the Sierra Oscura, in the eastern part of Socorro county, where the outcrop is traceable for a distance of 10 miles along one of the dikes, the protruding masses of ore being in places 60 ft. thick and exposed for 300 ft. and more. The deposits of Lincoln county, almost as large, lie a little farther to the east. This ore is of very good grade, the percentage of iron running up to 66.4 per cent., the sulphur down to 0.07 per cent., and the phosphorus

down to 0.09 per cent. on what is known as the Jones' iron in the Oscuras. Other samples from these same fields show practically no phosphorus, only traces of sulphur, and no titanium.

COPPER

Although the production of copper during 1908 fell short of that for 1907, due entirely to the drop in the price of metal, nevertheless copper has become a decidedly important factor in the mineral industry of the Territory. Many millions of dollars' worth of development work was done in the Territory in the last two years, and the total reserves of copper thus opened up have become enormous. The most extensive development was in the southwestern and central western parts of the Territory, especially in the Burro mountains, the Organ mountains, the Mogollons and the Magdalenas. But in many other localities also development was carried on in a systematic manner. Rotary and churn drills were used in several localities, especially in the Grant county properties, and have been instrumental in developing the large deposits of the Burro mountains and elsewhere.

Geographically the copper ores are widely distributed over the Territory, commercial bodies of ore being found in 16 counties out of the total of 24. Geologically the ores have been divided by Dr. Fayette A. Jones into those from deposits in the pre-Cambrian; those from the later Tertiary series; and those of the Permo-Carboniferous and Jura-Triassic formations. Nearly all of the active producing localities are in formations belonging to post-Cretaceous time, and the ores come from porphyritic masses with disseminated copper minerals; from carbonate and oxide replacements in limestone; and from fissure and contact veins containing both primary sulphides and oxidized ores according to locality. Some of these deposits have long been known, as those at Santa Rita, which are the oldest worked copper deposits in the United States, the native copper being shipped to the City of Mexico more than 100 years ago, and mined almost continuously since. These deposits are still among the largest producers. The copper ores always carry some gold and silver, and in some of the camps, as at Pinos Altos, lead and zinc accompany them also. The ores of Grant county generally, and especially those of the Santa Ritas and Burro mountains are very pure and carry only small amounts of silver and gold, while at other localities a little farther to the north and to the east, as, for instance, the ores in the Cooney district of the Mogollon mountains, carry much silver and gold, and are always uniformly high in these metals.

The production of the Territory as a whole amounted to just about 4,900,000 lb. of copper during 1908 as near as figures at present obtainable indicate. This tonnage came principally from the camps

of Grant and Socorro counties with smaller amounts from Santa Fe, Dona Ana, Luna and Sierra counties. Among the largest producers and heaviest operators in the Southwest may be mentioned the new Savannah Copper Company, which has taken over and consolidated the properties of the Comanche Copper Company with its smelter at Silver City and its railroad to the mines, and the Copper Gulf properties; the Chemung Copper Company operating with a large force of men at Tyrone; the Burro Mountain Copper Company at Leopold where the big concentrator is kept busy on 3 to 4 per cent. ores; and the Azure Mining Company, all of Grant county.

The copper ores in the Tertiary, known as the "Red Beds" occur in many places, and have again during 1908 been the subject of investigation on the part of several companies. Their form is usually carbonate and oxide, but frequently metallic, and their tenor in copper is near 2 per cent., and in places rises higher, coming nearer to 3 per cent. The problem of their reduction seems near solution at the present time.

GOLD

The unsettled condition of the copper market had its effect in the search for gold and the attention was given to the old and well known silver mines, many of which have been reopened and equipped with new or renovated mills. Gold comes from both lodes and placers. The placer production remained about the same as formerly in the northern counties. The new placers recently discovered at Hachita have not had time thus far to add materially to the production. Operations at Hachita were rather extensive, so far as prospecting was concerned, but the regular development has proceeded with caution.

Dry washing was tried in this section on several pneumatic machines. It has also been tried on some of the older placer ground in Santa Fe county, but so far with no marked success.

The shipment of telluride ores from Sylvanite will, no doubt, add materially to the production of gold during 1909, but shippers had barely commenced to send out their ores regularly before the end of the year, so little additional supply can be credited to that section for 1908. The great source of the gold is the gold-quartz ore of Socorro county, and the gold-copper ores of Grant and Socorro counties. The Last Chance mine in the Mogollons, the largest individual producer of the precious metals in the Territory increased its output almost 50 per cent. during the year. The Rosedale mill, one of the best known cyanide mills in the Territory, was remodelled and enlarged and is working at full capacity again. The gold ores of the Mogollon mountains were extensively developed, and several powerful companies were organized for the purpose of exploiting that section.

Six mills are now being put into commission in the Territory, three of them being cyanide mills.

A large part of the gold produced is from the copper-gold ores and since these were cut down on account of the copper, the production fell short of that for 1907, notwithstanding the fact that the production of gold ores increased. The total production has been estimated at 10,600 oz. fine, or \$19,100.

Owing to preparations now under way in the southwestern and central western parts of the Territory together with those of the counties in the north central part, the production of gold should be more than doubled this year, even though no more than the normal amount of copper-gold is produced from Grant county during 1909. A large amount of exploration and development work is conducted in the Mogollons, Hillsboro, Jicarillo, Lordsburg, and Central districts, in the Organ mountains, and in the Sangre de Cristo mountains and Colfax and Taos counties, to develop gold properties. Most of the producing sections are in post-Cretaceous formations, the same as copper, but several prospects which show promise of becoming extensive producers are in the pre-Cambrian, as, for instance, those in the Sandias, but in this formation the ore seems to be of lower grade, averaging, perhaps, \$3 to \$4 gold per ton.

SILVER

The silver production which is estimated at 332,000 oz. fine, showed a reduction from the previous year. The silver ores are found associated with the other ores, principally lead and gold, but also frequently with copper in rather large proportion. The curtailment in the production of silver was brought about by the low production of copper and lead. In several important instances, however, systematic investigation of properties for silver alone were undertaken during the year, and encouraging results were obtained. The localities most influential in the production of silver were the Mogollons, the Organs, Pinos Altos, Steeple-rock, and the camps of the Central district, though smaller shipments went to make up the amount stated. Among the important undertakings based largely upon the silver content of the ores should be mentioned the Boston Cerrillos Mines Company, an incorporation now commencing extensive improvements on the old Cash Entry mine near Cerrillos. The Last Chance mine in the Mogollons, is by far the largest producer of silver.

LEAD

Donna Ana, Sierra, and Luna counties were the most active in the production of lead, which amounted to about 1350 tons of metal including that from the Magdalenas. Development work was carried on even where shipments were suspended. The largest individual producer was the

Stephenson Bennett Consolidated Mining Company, operating upon lead-silver ores at Organ in Donna Ana county. The company is producing ore at the rate of 300 tons per day. Shipments went regularly forward from the mines in the upper Magdalenas, all carbonate ore derived from development work. The Ocean Wave mill at Hermosa was built during the year.

ZINC

The mines at Magdalena, in Socorro county continued to ship zinc carbonates, though the camps in the southern portions of the Territory were mostly closed down except for development work which was pushed with vigor in a few places. In Magdalena the leasers in the Kelly mine shipped 5300 tons in seven months, sending out a car a day at the close of the year. The Kelly has been equipped with a 100-ton concentrator using the Sanders flotation process to separate the zinc sulphides. In the Graphic systematic development work was conducted continuously, with a force of from 20 to 40 men, still further blocking out the already enormous bodies of ore exposed within the ground.

Even a cursory review of the mineral industry of New Mexico should not fail to mention the turquoise found and produced in three principal places in the Territory. The most famous locality is that of the Burro mountains. The mines at Cerrillos were reopened, and in the southwestern part of the Territory a new find commenced to market turquoise.

Natural cement, known as the "white sands," is proving a most noteworthy addition to the list of mineral products. Meerschau is now regularly produced in Grant county, and has been found of excellent quality in three places in that county.

Texas

BY WALTER E. KOCH* AND J. K. PRATHER†

There will not be much metal mining in Texas until the legislature passes fair and equitable laws, and gives the miner an even chance as in other States. The sooner this is done, the better for Texas mining. There is some silver mining at Shafter, Presidio county, where about 300,000 oz. of silver are obtained annually from an oxidized limestone-replacement deposit; these ores also contain some lead, but it is not recovered.

From time to time miners come to El Paso with copper ores from the Gaudalupe mountains and the Sierra Blanca range to the east of El Paso. Some veins have been traced and several shafts have been sunk on copper deposits in that part

of the State. In northern Texas copper has been found in the Permian beds.

The tin prospects on the eastern slope of Mount Franklin, about 10 miles north of El Paso, have been further developed with very gratifying results, and it is quite probable that a concentrating mill and a smelter will soon be erected. The granite masses in places have been found to be impregnated with cassiterite, which varies in color from very pale to very dark crystals. This fact doubtless has caused it to be overlooked or mistaken for other minerals, and careful and constant assaying is required since the use of a microscope with a 100-diameter object-glass is necessary to detect the various forms in which the cassiterite occurs.

Cinnabar is mined at Terlingua, in Brewster county, about 12 miles from the Rio Grande river, and about 100 miles from Marfa station. The ore is found in veins and pockets in the Cretaceous limestone, and is mined chiefly by open cuts; it is smelted in wood-fired furnaces, and the quicksilver shipped to the railroad in flasks. There are several companies owning mines in this district, but only one is reported to be producing now. Brown-hematite ore occurs in 19 counties, and in Llano county there is a deposit of magnetic and specular ore.

At Baringer Hill in Llano county the Nernst Lamp Company still continues to mine a few hundred pounds of the rare minerals, allanite, cryolite, fergusonite, gadolinite, polycrase, etc.

Coal is mined in Webb, Maverick, Houston, Shelby, Wood, Hopkins, Wise, Parker and Erath counties. Lignite is mined in Milam and Robertson counties. Some of the companies are: the Rio Grande Coal and Irrigation Company, at Minera, Webb county; the Cannel Coal Company, at Darwin, Webb county; the Carr Wood and Coal Company, near Lytle, Medina county; the Maverick County Coal Company, near Eagle Pass, Maverick county; the Bertetti Coal Company, near Lytle, Medina county; the Rio Bravo Coal Company, near Eagle Pass, Maverick county; the Glenn-Relto Coal Company, Bishop, Bastrop county; the Worley mine, Rockdale, Milam county; the Black Diamond Coal Company, Rockdale, Milam county; the Lignite Eggett and Coal Company, Rockdale, Milam county; the Central Texas Mining, Manufacturing and Land Company, near Calvert, Robertson county; the Houston County Coal and Manufacturing Company, at Crockett, Houston county; the Timpon Coal Company, near Timpon, Shelby county; the North Texas Coal Company, near Alba, Wood county; the Como Coal Company, near Como, Hopkins county; the Wise County Coal Company, near Bridgeport, Wise county; the Bridgeport Coal Company, near Bridge

*Mining and metallurgical engineer, 827 Guaranty Trust building, El Paso, Texas.

†Mining engineer, 301 North Oregon street, El Paso, Texas.

port, Wise county; the Texas Coal and Fuel Company, Rock Creek, Parker county; the J. S. Young mine, Keller, Parker county; the Texas & Pacific Coal Company, Thurber, Erath county; the Strawn Coal Mining Company, near Strawn, Palo Pinto county, and the Smith-Lee mine, near Cisco, Eastland county.

The lignite beds in Texas are Eocene in age and extend over a belt 200 miles long. The Cretaceous coals are found in the Eagle Pass coalfields which extend into Mexico, and for 8 miles north of Eagle Pass. The Carboniferous coals are found in a small area in El Paso county and in a much larger area in north-central Texas, stretching from a few miles south of the Colorado river in Concho, McCulloch, and San Saba counties in a north easterly direction to the Red river.

Asphalt is found in the vicinity of St. Joe, Montague county, and at Muenster, Cooke county in a sandstone near the Cretaceous-Carboniferous contact. In Anderson county the asphalt occurs in the Tertiary (marine Eocene) sediments. In Uvalde county the asphalt has been developed to some extent by the Uvalde Asphalt Company. The asphalt occurs both in a bituminous limestone and in a bituminous sandstone.

Sulphur and salt have been found in El Paso county, but these deposits have not been developed as yet. Gypsum is found in northern Texas and also west of the Pecos river. Fire clay occurs associated with the coal and lignite; there are also many useful clay deposits in many widely separated parts of Texas. Heinrich Ries has published a report on the Texas clays.

Wyoming

By HENRY C. BEELER*

As were all her sister States whose mines are developing, Wyoming was hard hit by the business depression of 1907, and some of her mines were almost put out of business for the time being. Since the election, however, many of these were reopened, and are at least doing their annual work and making preparations for an active campaign in 1909.

COPPER

Copper is the principal mineral in Wyoming, being noted in all the State camps either as the main ore or the carrier of other metals. Production was low owing to almost impossible transportation conditions, which are gradually being overcome as the old and new railroads are extended throughout the State. The only smelter in the State is at Encampment, where the Penn-

Wyoming Copper Company controls the Ferris-Haggarty and Doane-Rambler mines. The company built 44 miles of railroad from Walecott on the Union Pacific Railroad to Encampment, and ran the greater part of the year. It is now doing development work only in its two mines for a larger record during 1909. Several new strikes were made in the Encampment district, that of the West Virginia-Wyoming Company, in Battle Basin, being the most notable, as it proves the further extent of the contact ores of the region and shows the way for others.

After about six years of expensive experimenting, the Rambler Mining Company, controlling the Great Rambler mine, in the Medicine Bow range in Albany county, succeeded in separating the platinum and palladium which occurs in commercial quantity in the copper ores; during the fall of 1908 the company had a force of men reopening up the property. The building of the Laramie, Hahns Peak & Pacific Railroad from Laramie to the North Park coalfields brings transportation within a few miles of this and the adjacent mines on Lake and Douglas creeks, as well as the Shawnee and properties on French creek and the Snowy range where heavy copper indications are being quietly developed and proved.

The Williams-Luman Mine at Depass, on Copper mountain in Fremont county, is opening up the largest body of copper ore yet discovered in Wyoming. Little is heard about it as no stock is sold and none is for sale. About 2000 ft. of development work showed a huge ore-body, 80 ft. wide, the length not being proved. At 485 ft. depth, copper oxides and metallic copper were noted, as at the surface and the accompanying gold-bearing streak of about 6 or 7 ft. is much in evidence. A gas-producer plant to use lignite was installed for additional power.

The Boysen power dam in the Big Horn cañon at the west end of Copper mountain is relied upon for power for the whole adjacent mining territory, as well as for the nearby towns. As all the difficult work of installation is practically completed, the plant should be in operation by the spring of 1909.

Copper prospecting proceeded over a greater territory than ever before, and more genuine development work on better showings is the result of this systematic work. It is more generally recognized that copper is the main mineral to be found in Wyoming and the low grade of the ores, conditions of occurrence and method of development are better understood, with marked improvement in results.

GOLD

Almost all the work on gold properties

this year was development and preparation. The Miners Delight mine in Fremont county shut down owing to expense of fuel. The Popo-Agie oil and Power Company is installing a plant to supply electric power to this and the other mines of the South Pass gold district, using the oil of the Lander fields as fuel, with the plant located at the old Murphy wells.

At Centennial, Albany county, Copper mountain, the Wind River ranges, South Pass and Atlantic, in Fremont county, all reports showed activity in the gold properties but production during the year was low.

Active placers were reported from the Little Big Horn, Sheridan county, Willow Rock and Twin Creeks, in Fremont county, Green and Snake rivers in Uinta county, Snake river in Carbon county, Sundance in Crook county and Douglas and Lake creeks in Albany county. The American Gold Placer Mining Company installed a steam shovel, prepared its pits and worked up to the last workable day of the season but operations were frozen up before a cleanup was complete. Preliminary tests were satisfactory.

COAL

Coal showed the largest production, as usual, but not much increase as compared with 1907, owing to a quiet strike which tied up the mines a part of the year. New mines are opening in the newer sections of the State, and those opened in 1907 are showing a uniformly larger tonnage than was anticipated last year. The lignites of Wyoming are in great demand for local fuel and in adjacent States as the new gas producers utilizing these fuels have made their use possible in plants where formerly they were useless.

IRON

Production proceeded steadily in the Colorado Fuel and Iron Company mines at Sunrise, Laramie county, the total for 1908 exceeding that of 1907. Additional prospecting in this vicinity showed a greater area than this deposit was supposed to cover, and the presence of iron operators from eastern fields, bidding for lands, indicates that other mines and properties again have a chance of being opened up. The Bradley Peak and Rawlins deposits, in Carbon county, were also under inspection but nothing definite was given out for publication. Prospecting for iron is also going on in other sections of the State and samples submitted indicate that other commercial iron areas will be opened. A shipment of chrome iron was made from Converse county.

ASBESTOS

Asbestos will be an important item in the mineral reports of Wyoming for years to come. Commercial chrysotile

*State geologist, Cheyenne, Wyoming

asbestos was practically developed in 1908 by the North American Asbestos Company on Casper mountain, Natrona county. A mill will be erected in the spring of 1909 and commercial production will begin. There is no doubt as to the quantity and quality of the product; the fiber shows up to 4 in. in length, 2 in. is not uncommon, and fiber an inch long is common. Practical tests amply demonstrated the spinning and workable qualities of the fiber, though at first only the rougher grades will be regularly produced. The asbestos occurs in serpentine in granite and schist, showing up to 200 ft. wide. Solid asbestos rock was shown in the main workings, 20 ft. wide and the full width not cut at that time. A similar asbestos appears at Smith creek and Deer creek near Casper mountain, and part of this is under development by the same company.

SULPHUR

The Wyoming Sulphur Company opened up a large deposit of sulphur at Thermopolis, Fremont county, and erected a plant to treat the ore and make commercial sulphur. This is a hot-springs deposit, similar to the Cody and Sunlight deposits in the same county, but more extensive and accessible. The ground was proved by drilling and tests before the works were planned.

OIL AND GAS

More drilling was done in 1908 than for a long time in the different oil fields of the State. In the Salt Creek field in Natrona county, one gusher was struck, and the rigs were moved to another location where drilling is now going on. The Popo-Agie Oil and Power Company is drilling near the Murphy wells for oil, for fuel for the new power plant. A pipe line is contemplated from the wells to Hudson, the nearest railroad point, and additional rigs will be put into commission as soon as they can be advantageously placed.

A gas gusher burned for a year near Basin, Big Horn county, but was finally capped. Additional wells were drilled in the vicinity to furnish local consumers and further to test the fields. At Byron and Garland, in the same county, oil and gas were struck; drilling still goes on.

The Uinta county fields are more active than for several years with indications that production is to be permitted, and these high-class oils to be put on the market. High freight charges have hitherto kept the production down and stopped production.

All things considered, Wyoming held its own during 1908, and while location work and patenting of mineral, oil and coal lands all were seriously hindered and the miners were put to much unnecessary expense and trouble by the over-zealous

agents of the National Forest and Land departments, whose various reserves and "withdrawn" areas cover most of the State, general prospecting was active and productive of good results.

Vermont and New Hampshire

By GEORGE A. PACKARD.*

Very little copper ore was mined in Vermont in 1908. The Eureka mine at Corinth was closed during the entire year, and little work was done on the nearby property which has been partially developed by the Corinth Copper Company.

At South Strafford the Vermont Copper Company continued equipping its mine. Power development has been seriously delayed by winter and spring freshets, which twice carried away the dam on the White river when in a partially completed stage. This power plant, which is located at Sharon, is now ready for operation. The station is built for 750 h. p., but the equipment so far installed includes water-wheels and generators for only 500 h. p. This is transmitted at 6600 volts, 3-phase, and the motors, locomotives, hoists and pumps, have been tested and found satisfactory. The flues and stack are completed, and the furnace will be blown in early in 1909. It is expected that between 300 and 400 tons of ore per day will be treated at the start. Plans for a sulphuric-acid plant are being prepared, and surveys for a railroad to connect with the Boston & Maine system are completed.

The old Milan, N. H., mine, from which pyrite and a little copper ore were shipped "in the '80's," has been reopened, and several carloads shipped are said to have run 5 per cent. copper, and as high as 50 per cent. silica.

South Dakota

By JOHN V. N. DORR†

The mining industry in South Dakota has been fairly prosperous in 1908. No new properties were developed but the principal mines were in steady operation. As the production is mainly gold, the drop in the price of silver and other metals has made no difference, and the principal difficulties to be met have been the gradual decrease in value of the ore mined at many of the old properties, together with the somewhat increased cost of labor due to the adoption of the 8-hour day.

*Mining engineer, Wakefield, Mass.

†Metallurgical engineer, Pluma, S. D.

The use of electric power has been extended, so that the only steam power in use in the northern Black Hills is at the Homestake properties; indeed there also electric power is now in use at the three stamp-mills, the slime plant and the re-grinding plant. Both the Consolidated Power and Light Company, with a steam-electric plant, and the Black Hills Traction Company, with a hydro-electric plant, are loaded to their capacity, and are planning to increase their output. It is probable that in the summer of 1909 a hydro-electric plant generating from 5000 to 7000 h. p. will be built on Spearfish creek. The saving made by the use of electric power has been a material factor in maintaining the present production.

THE HOMESTAKE COMPANY

The Homestake company has operated all its stamps continuously during the year and has made a production, as given by the State mine inspector's report, of \$6,000,000, which is considerably larger than that of any previous year. The company increased the November dividend from 50c. to 75c. per share, the largest amount ever paid, but in December it was returned to the former figure. Among the improvements made in 1908 have been the constructing of a large reservoir, the rebuilding of the foundry and the equipment of it with all modern improvements, and the installation of a re-grinding plant to handle the coarsest sands from the batteries, the reground pulp passing over plates before going to the cyanide mills. The equipment consists of six grinding pans and a 5x14-ft. tube mill. The operation of the plant should give some interesting data as to the comparative efficiency of the two mills for regrinding under conditions obtaining here. The plant has proved very successful.

SILICIOUS ORE MINES

The Mogul, the Golden Reward, the Imperial, the Lundberg, Dorr & Wilson, the Reliance and the Wasp No. 2 properties have operated their mills steadily during the year.

The Imperial company reached lower quartzite in the Dakota shaft during the summer and has drifted several hundred feet in the quartzite and found some ore. If the further prospecting of the lower quartzite should disclose orebodies as strong and rich as those found in the shale above, it will mean a much longer life to the district.

The Mogul company, operating its remodeled mill at Pluma, has averaged over 320 tons per day and reached a maximum of 388 tons in October.

The Golden Reward company, which installed a Chamberlain press for handling its slimes early in the year, has recently

let a contract for a Moore-filter installation and expects to increase the tonnage handled greatly.

The American Eagle Mining Company started a 200-ton mill during the summer, but found the mine developments were not adequate to operate this at full capacity and so closed down awaiting further development.

In the Garden City district the North Homestake Company operated its 40-stamp mill steadily during the year, and the Minnesota Mines Company, with a mill equipped with slow-speed Chilean mills, has commenced operations.

GALENA DISTRICT AND OTHER DISTRICTS

The Gilt Edge-Maid company, working a very large body of low-grade porphyry and crushing dry to 3/16-in. size, has run regularly, milling about 200 tons daily. This company is believed to have established a record for the Black Hills for low cost of mining and milling, for the cost is reported to be approximately \$1 a ton.

The Golden Crest company, also mining in porphyry near the Gilt Edge-Maid, is building a 200-ton mill to crush with stamps, regrind with tube mill and treat the whole product by the Moore process. This is the first company in the Black Hills to erect an all-sliming mill. As the ore is very soft, the cost of complete slime treatment should not exceed that of a sand-and-slime treatment, and the recovery will undoubtedly be higher.

The Branch Mint company started its 120-stamp mill, but found, as so often happens, that it had gone ahead without sufficient mine development, so the mill was shut down after a short run. The property is now leased to an operating company which is running part of the mill on an old dump, while the mine is being developed.

Considerable work has been done in the southern Black Hills during the year, and the Standly company, at Rochford, has been running its mill while doing development work that has extended the limits of its orebody. It promises to become one of the big mines of the Hills.

METALLURGY

The problem of the successful treatment of the "blue" ores of the district, which as they are worth only \$5 to \$7 per ton, are too low in grade to stand shipment to outside smelters, has received considerable attention. Renewed efforts have been made to obtain a better extraction by the use of other chemicals with cyanide. Some very promising results have been obtained, but nothing has reached a commercial basis. Roasting will give a good extraction on much of this ore, but not on all, and it is considered too costly for the grade of the ore.

The Black Hills will shortly be the place *par excellence* for the inspection of slime processes, for with the mills now building, there will be in operation four Moore plants, one Merrill sluice filter-press plant, one closed-type filter-press plant, two decantation plants, one Burt press, one Chamberlain press and a Butters plant.

In closing it may be of interest to note the influence of Black Hills practice on slime treatment. The Merrill sluicing press was first operated at the Homestake mill and the first successful installation using a submerged filter plan (a Moore plant) has been in continuous operation at the Lundberg, Dorr & Wilson mill since February, 1904.

Utah

SPECIAL CORRESPONDENCE

At the beginning of 1908 the outlook for the mining industry in the State was not bright. As in other States, the financial depression had a far-reaching effect. However, the ore market at Salt Lake was glutted all through the year owing to the closing down of the United States, Highland Boy and Bingham smelters. The smoke question was the chief cause of the closing of these smelters, although there were other contributory factors, among which might be mentioned the fact that the Bingham Consolidated practically reached the end of its ore supply.

Among the matters which attracted attention was the attitude of the Utah Consolidated in connection with its contract with the American Smelting and Refining Company for the treatment of ore. The present contract expires in March, 1910. The Utah Consolidated, before renewing its contract, began looking into the advisability of building a smelter of its own. The cost of transporting ore from Bingham to Garfield, under an old contract with the Denver & Rio Grande railroad is 40c. per ton; other companies pay only 25c. per ton. The Utah Consolidated secured options and smoke easements on 30,000 acres of land in Pine cañon, Tooele county. By building a smelter here the ore could be transported by aerial tramway, thus saving most of the amount at present paid for freight to Garfield. The American Smelting and Refining Company was opposed to the erection of another smelter, fear of a competitor being among its chief objections. There was a great deal of activity displayed on both sides; some difficulties were encountered from the fact that there were a few influential stockholders of the Utah Consolidated who were also interested in the American Smelting and Refining Company. However, before the date of expiration, Sept. 30, the Utah Consolidated

had exercised its options and had completed plans for its smelter.

Toward the end of 1908 it was announced that the Utah Consolidated had let a contract for the erection of a smelter, to be completed by April, 1910. According to the latest plans this smelter is to be one of the constituent plants of the newly organized International Smelting and Refining Company.

BINGHAM

The Utah Copper Company completed its Garfield mill in 1908 and operated at nearly full capacity. This company owns 200 acres of mineral ground in the central part of Bingham. The area developed to date includes about 72 acres. The thickness of the orebody has not yet been determined, but the work to date shows an average depth of 310 ft. The ore averages about 2 per cent. copper, 0.15 oz. silver and 0.015 oz. gold per ton. To the depth of present development, the ground promises an average yield of 1,000,000 tons of ore per acre. Below the depth included in this estimate is a zone of lower-grade ore which averages 1.5 per cent. copper; this, as indicated by diamond drills, contains 40,000,000 tons of ore.

The company is mining from 6000 to 7000 tons of ore per day, about 80 per cent. of which is secured from open cuts. At the mine the company operates 20 locomotives, 125 dump cars of 6 yd. capacity, and six steam shovels. There are about 10 miles of standard-gage railway laid with 65-lb. rails. The compressor plant has a capacity of 300 h.p. All repair work for locomotives and machinery is handled in a fully equipped machine shop.

The Porphyry mine, of the Boston Consolidated covers about 156 acres, adjoining the Utah Copper on the south. A large proportion of this area is underlain with mineralized monzonite, similar to the ore of the Utah Copper, but containing about 1.5 per cent. copper. The equipment for stripping and milling this ore is capable of handling 15,000 tons per day. During 1908 the company put additional units into operation in the mill, and expects to be running at full capacity early in 1909.

The operations of the Boston Consolidated have not been as successful as was anticipated because the ore mined was not so high in grade as had been hoped. The high content of pyrite caused the grade of the concentrates to fall below what had been expected. This led to further prosecution of underground mining in order to get below the zone of oxidation in the quickest manner. However, there is no question as to the successful outcome of the operation.

The property of the Ohio Copper Company adjoins that of the Utah Copper on the east and the Boston Consolidated on the north, and covers an area of 120 acres. There are estimated to be 13,500,000 tons of ore above the present transportation tunnel. The copper content of the ore is

between 1.6 and 1.75 per cent., in addition to which it carries about 10c. in gold and 3c. in silver per ton. The company did little actual work in 1908, owing to Heinze's difficulties.

The Garfield plant continued to experience metallurgical difficulties, one of which pertains to the handling of the very fine concentrate produced by the Utah Copper Company and the Boston Consolidated. The inability of the smelter to handle all the tonnage offered has led to a large accumulation of unsmelted ore in the district.

The Yampa mine is an important producer of sulphide ore. The ore is practically self-fluxing, requiring only the addition of a small quantity of limestone. During 1908 there were installed at the smelter in Bingham cañon, two converter stands with six converter shells of 84x136 in. diameter. Toward the end of the year the mine was working an output of from 700 to 800 tons of ore per day. The smelter treats the tonnage of the mine and about 200 tons per day of custom ore.

PARK CITY

The unfavorable prices of lead and silver during 1908 had a depressing effect on the Park City district. The chief activity in 1908 was in development work, and several promising orebodies were uncovered. This was especially true of the properties in Thaynes cañon, near Brighton. In that section the Copper Apex, Keystone, Uintah Treasure Hill, New York, Wabash and Silver King Consolidated displayed activity.

TINTIC

The Tintic district still holds the distinction of having more dividend-paying mines than any other district in the State. Early in 1908 the mines of the district suffered much by the closing down of the Salt Lake smelters. Relief was furnished through an amicable agreement between the farmers and the lead smelters.

An outlet for the ore of several mines was furnished with the blowing in of the smelter of the Tintic Smelting Company, at Tintic, on July 24. This smelter, which is controlled by Jesse Knight and associates, has a capacity of 350 tons of ore per day. In October, operations ceased temporarily, lack of electrical power supply being given as the cause. It was also hinted that there were some metallurgical difficulties. Three lead furnaces were in operation as the close of the year. One copper furnace is nearly ready to start up, and another lead furnace is under construction.

In October, a syndicate, headed by Jesse Knight, obtained a controlling interest in the Opex group, and organized the Opex Consolidated Mines Company.

MERCUR

The Mercur gold district felt the finan-

cial depression to a less extent than did the other mining districts of the State. Little of exceptional note transpired during 1908. The Boston Sunshine Gold Mining Company reconstructed the mill of the old Sunshine mine and is adding much new equipment preparatory to cyaniding the refractory clayey ores of this once famous mine.

The dividends paid to date by the Consolidated Mercur Gold Mines Company, and the old De Lamar and Mercur companies, totals \$3,385,312.

Idaho

BY ROBERT N. BELL*

The mining industry of Idaho during 1908 has experienced a rather dull year. A large tonnage of ore was mined and treated, but owing to the low metal prices that prevailed throughout 1908 profits, as compared with previous years, were seriously curtailed. Such development work as was in progress during 1907 was stopped at the approach of the money panic, and a great deal of this work has not been resumed. This reduced the number of men employed in 1908 about the mines and mills of the State fully 20 per cent. as compared with 1907.

SHOSHONE COUNTY

In the Cœur d'Alene district, two of the principal producers, the Hecla and Morning mines were closed down for the first six months of the year owing to lack of market for their ores; the Last Chance mine was also idle for two months of the year. These properties threw out of employment 1000 men; they resumed full operation in June, and have since been employing the normal force of men and making the usual production of ore. The Hercules, Standard-Mammoth, Bunker Hill & Sullivan, and Snowstorm mines were operated continuously. At present the producing mines of this district are employing about 2000 men, while the smaller producers and development enterprises of the district provide employment for approximately 1000 more.

The notable event of 1908 in the Cœur d'Alene district was the completion of the Idaho-Northern railway up the north fork of the Cœur d'Alene river from Enaville, on the Oregon Railway and Navigation Company's road, to Murray on Pritchard creek. This will give railroad transportation to the well mineralized section of the Cœur d'Alenes, known as the north side, and is likely to result in an important increase in mineral traffic during 1909, for on the north side there are a number of very promising deposits of silver, lead, gold and tungsten.

The construction of the Chicago, Mil-

*State Mine Inspector, Boise, Idaho.

waukee & St. Paul railroad down the St. Joe river and extending through the south border of the district is approaching completion. This road will prove a great aid in the development of the numerous rich copper, gold and lead-silver prospects in that part of the district and will greatly enlarge the productive area of the Cœur d'Alene district.

At Burke, the old Tiger Poorman mine, owned by the Federal company, after being developed to a depth of 2200 ft. through a vertical shaft was closed permanently. Its famous pumping station has been dismantled, and the mine has been allowed to fill with water. On the bottom level, the oreshoot had contracted in length and width so that it was no longer profitable to work. However, the mine still contains a big, strong root of an oreshoot, and it is a pity that a winze has not been sunk in the orebody to a depth of 300 ft. or 500 ft. in order to see if the shoot did not enlarge as has been the case at great depth in other oreshoots in this district.

At Mullan, the development of the new oreshoot discovered at a depth of 800 ft. in the Star mine has disclosed another large source of high-grade concentrating lead-silver ore. This is a new oreshoot on the Morning fissure which traverses the full length of this property. The shoot is 500 ft. long and from 5 to 15 ft. wide; the ore is of about the normal grade characteristic of the silver-lead ore in this part of the district. Extensive plans for further development at great depth are being made, and this property will probably become in time a large producer.

In addition to the Star, other promising ore discoveries are the Alice mine at Ruddy gulch, the Cooney mine at Burke, the Ambergis mine at the head of Nine Mile creek, the Bear Top at Murray, and the Caledonia mine near Wardner and on the foot-wall side of the Wardner lode. At present all these properties can ship high-grade crude ore from bodies of considerable size. There are also a number of other promising properties that are being operated, and, as the old mines gradually drop out, their place will doubtless be taken by new properties that will maintain the present output of the district.

The principal producers, including the Bunker Hill & Sullivan, Last Chance, Hercules, Hecla, Standard Mammoth, Morning, Gold Hunter and Snowstorm mines, are all in splendid physical condition and producing their normal tonnage. In 1908 the total yield of these mines was approximately 1,250,000 tons.

In spite of their great depth, the big lead-silver mines continue to maintain a comparatively high-grade ore; in fact, the average yield of the ore is probably a little higher now than at any period in the history of the district. The bulk of the ore is, of course, concentrating ore and averages about 8 per cent. lead and 5 oz. silver per ton for the whole district.

The operators are seriously concerned over the proposed cut in the tariff on lead ores. Any reduction would have a large effect on the profits of the Cœur d'Alene companies, and would probably be the cause of a retrenchment in the wage scale, for while the silver in the ore is a large item in reducing the cost of producing the lead, the mines are getting very deep, and

mines had a hard struggle for existence until a depth of several hundred feet was reached. The profits figured against the total expenditures on the mines do not show more than a reasonable margin, and at several of the largest producers much of this margin would be wiped out by the removal of the present tariff rate.

An important economy has been intro-

were large owing to the crushing of much waste rock with the ore. Owing to this sorting the crude-mineral shipments of the district in 1908 became much larger than in 1907.

The Snowstorm copper mine produces nothing but shipping ore. Its lower levels developed in a magnificent manner during 1908, and the mine made the largest out-

MAP OF COEUR D'ALENE MINING DISTRICT

consequently becoming more expensive to operate than formerly.

The principal producers are nearly all in bonanza at this time, but they have involved large outlays in preliminary development and plant equipment. Several years were required to develop these mines for nearly all the veins in the district were poor at the surface, and some of the

duced at all the big mines by adding a picking plant near the portal of the main adit. The ore is roughly sorted into shipping ore, concentrating ore, and clean waste, the shipping ore being sent direct to the smelter, and the waste returned to the mine for filling. This sorting has materially increased the extraction in the mills by reducing sliming losses which formerly

put in its history, shipping a total of 100,000 tons of ore, containing slightly over 90 lb. or 4½ per cent. copper and 6.14 oz. silver per ton. The mine is paying dividends at the rate of \$45,000 per month and has ore resources for several years ahead that will yield this rate of profit if present copper prices are maintained.

WOOD RIVER DISTRICT

Several of the mining districts of Idaho have experienced a very slack year in production; this is especially true of the Wood River district. In the Wood River field an unusually light output has been made owing to the lack of market and low metal prices, but nevertheless 1908 has been a year of great preparation, as five

During 1908 the Idaho Consolidated property was equipped with a hydro-electric power plant of ample capacity.

At the Independence mine, near Ketchum, a new mill having a capacity of 100 tons per day is being installed; the machinery is all on the ground. An electric transmission line was constructed from Hailey to this property; over this

erected. The future of this field is bright, and promises a largely increased yield of rich ore in 1909.

CUSTER COUNT.

In Custer county the White Knob mine, owing to lack of market for its ores, was idle during the greater part of 1908.

At Loon creek, the Lost Packer company successfully operated its 100-ton

MAP OF COEUR D'ALENE MINING DISTRICT

new mills were building in the district. Two of these, the Idaho Consolidated mill at Bellevue and the Cræsus mill, having a capacity of 100 tons per day and three miles west of Hailey, were completed. Developments on the bottom levels of the Cræsus mine, the deepest in the Wood River district, are magnificent. This argues favorably for the further development at depth on other fissure veins in this field.

the power to run the mill will be transmitted from the Cramer electric plant. The Independence has a reserve of high-grade ore estimated at 60,000 tons, and upon the completion of its mill in 1909 it should become an important producer.

A 100-ton mill is also being built at the Lucky Boy mine on Warm Springs creek, and at the Muldoon mine in the Muldoon district another 100-ton mill is being

smelter for 90 days during the summer, and produced some high-grade gold- and silver-bearing copper matte.

The Golden Sunbeam mine in the Yankee Fork district operated its 50-ton mill throughout the year and made a large output of gold bullion. This property has developed in a magnificent manner, and promises to continue a steady producer for a long time in the future.

LEMHI COUNTY

In Lemhi county the ore shipments from the lead-silver district were very light, due to low metal prices and the long wagon haul to the railroad. Several important discoveries were made during 1908, and a new independent smelting plant to treat the medium-grade ores of this district is in process of construction at Spring mountain. This should greatly encourage ore development in this part of Idaho.

At Indian creek the Ulysses mine resumed operation during 1908, and is again making an important yield of gold bullion.

The coal mines at Salmon City were developed during the year with a small force of men, and made a remarkable improvement; the local market was supplied by them with a desirable fuel, and unsuspected deposits that promise a big tonnage in the future were developed.

SILVER CITY DISTRICT

In Owyhee county the Silver City district is giving employment to a force of about 600 men. The old Delamar mine greatly increased its ore reserves and enlarged its milling capacity 50 per cent. during 1908. The Trade Dollar Consolidated mine is employing its normal force of men, but its operation has been somewhat interrupted during 1908 through tying the Boise Interurban railway onto its electric-power plant.

Considerable activity in mining development is shown in the district around Silver City that should result in important ore disclosures in 1909. The most successful new enterprise near Silver City is the Potosi mine, which has been developed to a depth of 300 ft. by three levels and is showing considerable reserves of rich ore. This property was equipped with a 20-ton mill, which began successful operation at the close of the year. The mine promises soon to develop into a good dividend payer.

The extension of the Northwestern railroad down Snake river will shortly be completed to a point 58 miles below Huntington. This brings the west slope of the Seven Devils range in close touch with railway transportation, and is already proving a great stimulus to the development of the rich copper deposits in that district.

ATLANTA DISTRICT

The Pettit mine in the Atlanta district of Elmore county was purchased from the original owners by the Bagdad-Chase Gold Mining Company, of Rochester, New York, for \$125,000. This property is equipped with a 20-stamp mill, which was profitably operated throughout 1908; 20 more stamps are being added, so that the mill will treat 150 tons a day. The Pettit mine is responding to development and is showing up a large tonnage of good milling ore.

The new mill of the Atlanta Mines company was tried out during the year, and found unsuited to the successful treatment of the extensive ore reserves of this property; the mill will require considerable remodelling in order to treat successfully this ore.

The ores of this district, on account of their mixed silver minerals, need very close treatment in order to obtain a good extraction, but the orebodies are large.

ELK CITY DISTRICT

The Elk City district, in Idaho county, has enjoyed a prosperous year and has given employment to a good many men.

The Buster mine in that district has been developed to a depth of 400 ft. on a 10-ft. fissure vein, containing ore that averages from \$10 to \$20 per ton. This mine is equipped with a 10-stamp mill and cyanide plant, that has been successfully operated throughout 1908, making a large production of gold.

In the Elk City district are many promising fissure veins, so that further work is likely to develop other producers. The district also contains some large deposits of low-grade gold ore that are likely to become mines of the Treadwell type, with proper development and equipment. It is also noted for extensive old-channel, placer deposits; some of the placers are quite favorable for dredging.

COAL

In the Fremont County coalfields, the Brown Bear mine was developed to a depth of 200 ft. during 1908. The coal is found to be of even better quality and of greater value than in the shallow levels above. This district is producing considerable high-grade bituminous coal and is supplying the local farmers; with railway transportation, the district would probably be capable of supplying the demands of the State for high-grade fuel.

PHOSPHATE ROCK

Idaho produced 5700 tons of high-grade phosphate rock during 1908. This came from the property of the San Francisco Chemical Company at Montpelier, Bear Lake county. Recent development of the phosphate deposits of this district tends strongly to confirm the opinion that this field will prove the richest and most important source of phosphate rock ever discovered in the United States.

STATISTICS

The total metal output of Idaho for 1908 based on the gross contents of the mineral shipped, is approximately: Lead, 208,196,159 lb.; silver, 7,636,271 oz.; gold, 65,175 oz.; copper, 10,080,506 lb.; zinc, 200,000 lb. The dividends distributed during 1908 by metal-mining companies operating in Idaho will approximate a total of three million dollars.

Nevada

By WILLIAM H. SHOCKLEY*

The Nevada output for 1907 was 711,339 oz. of gold, value \$14,707,658; and 7,767,510 oz. of silver, value \$5,074,281; a total value of \$19,778,938. I estimate the production for 1908 at \$20,000,000, viz., \$15,500,000 gold, and \$4,500,000 silver. This is lower than was anticipated, the shortage being due in part to the fall in the price of silver from 55c. per oz. in January to 47.5c. in December, 1908, and in part to the fact that the Goldfield Consolidated husbanded its ore. This company produced about \$700,000 in 1908 and should make a large production in 1909 with its new 100-stamp mill. In November the Goldfield mines stopped publishing their output, so their product for the last two months of the year must be guessed at.

DIVIDENDS

I have learned of the following dividends paid by Nevada mines in 1908:

Goldfield:

Engineer's Lease	\$555,000
Florence Annex	50,000
Forence Mining Co.	420,000
Little Florence Lease	750,000

LABOR TROUBLES AND LABOR

At the end of 1907 a bitter strike was in progress in Goldfield and nothing but the presence of Federal troops prevented mob rule. In January, 1908, under the protection of these troops, non-union miners began work in Goldfield. The strike was called off on April 3, and Goldfield is now an open and peaceful camp. The establishment of a State police at a special session of the legislature in January preserved the peace of the State. This action of the legislature was approved by the voters at the election of Nov. 3, 1908, and this vote makes it certain that future strikes will be conducted peaceably. Though wages have been reduced to the Tonopah scale—\$4 per diem for miners—in a number of the camps there were no strikes during 1908.

The riches of Goldfield and Tonopah have drawn white men from all over the world. This mixing of races is well shown by the nationality of the miners in

*Mining engineer, Palo Alto, Cal.

In the fall of 1908 both Hazen and Rawhide were destroyed by fire.

FINANCIAL

Early in 1908 money became easier and on Jan. 11 the smelters resumed cash payments for ore purchased. Two banks with small capital failed during 1908 in Rawhide, and in December the Round Mountain Bank, capital \$25,000, closed its doors. The receiver of the State Bank and Trust Company has paid a dividend of 5 per cent. to the depositors and *hopes* to pay more.

RAILWAYS

The Western Pacific is steadily constructing its line and in a year should have trains running across Nevada into San Francisco. The Bullfrog & Goldfield road was sold to the Tonopah & Tidewater in the spring. Many new railroads are projected, but no work was done on them in 1908. A branch line to the copper mines at Yerington is likely to be the first one built. Important freight reductions have been made by the Clark road in order to attract ores to the Jerome smelter.

METALLURGY

In southern Nevada, demands for electric power have steadily increased; 30,000 h.p. are now being developed at Bishop Creek, 113 miles west of Goldfield.

Dry washers of two kinds were tried at Manhattan and Round Mountain, but proved failures; it is stated that the ground was too moist.

Air-hammer drills, especially good in raises, are now extensively used and give great satisfaction.

Shattered rock, which cementing failed to solidify, defeated an attempt to prospect below the Red Plume shaft of the Tonopah Mining Company with a calyx drill.

Hydraulic mining is carried on at Round Mountain. At Rabbit Hole, near Lovelocks, high-pressure pumps are to be used for hydraulicking.

COPPER

In the past a small amount of copper has been produced from the ores of Nevada, 1,462,450 lb. in 1907. But 1908 marks the beginning of a big increase, and in 1909 Nevada will be an important factor in the copper market, for the Ely mines will produce a large amount of copper. The Steptoe concentrator, three units of which are already completed, is now handling 4000 tons of ore daily, and its smelter is turning out 3,000,000 lb. of copper monthly.

The mines at Yerington, Lyon county, have developed a large tonnage of copper ore. The most important company, the Nevada Douglas, owns a mile along a vein which shows ore up to 100 ft. wide. The Bluestone Mining Company reports 3,000,000 tons of 3-per cent. ore developed; and the Mason Valley Mining Company is showing its faith by building the town of Mason 3.5 miles south of Yerington. This company has 50 ft. of ore running from 3 to 10 per cent. of copper. At Ubehebe, Mina, and Luning nothing specially good has shown up. At Lodi, Nye county, a 100-ton smelter will start early in 1909.

GOLD AND SILVER

Esmeralda county is still Nevada's chief producer. Its yield was increased in 1908 by the 100-stamp mill of the Pittsburg Silver Peak Mining Company at Blair; this mill produced \$750,000 during the 10 months it ran, and should turn out more than \$900,000 in 1909. Goldfield's output was \$7,500,000 from 75,000 tons of ore. In 1909 Goldfield's product should be even larger, since the 100-stamp mill of the Goldfield Consolidated is expected to treat 600 tons daily and ship \$6,000,000 in the year. With the completion of this mill Goldfield has a daily milling capacity of over 1000 tons.

A well traveled road does not seem a promising place for prospecting, but several roadside mines have been found in Nevada during the last few years. The croppings of the first mine found at Manhattan had been worn by wagon wheels for more than 40 years. In 1908 the Lucky Boy mine near Hawthorne, and the Great Western south of Goldfield, both found close to old wagon roads, have

come into prominence through their rich ores. The Great Western is shipping its silver ore to the Belmont mill at Millers. A number of mines have been found near it; one of these, the Nevada Empress, has built a 35-ton Hathaway mill.

The Rawhide boom was faint early in 1908. A new rush began later, but was interrupted by the burning of the business portion of the town on September 4. More than 50 hoists are working in Rawhide, and it will doubtless prove a good low-grade camp.

In 1908 the Tonopah mines, in Nye county, produced about \$2,000,000 in gold and \$4,000,000 in silver. These mines have been seriously hampered by the fall in the price of silver and with a further fall many of them will be obliged to close; with silver selling for less than 50c. per oz., the Tonopah Mining Company is probably the only one that can make a substantial profit. The 100-stamp mill of the Tonopah Mining Company, at Millers, and the 40-stamp mill of the Montana Tonopah, at Tonopah, are both working ore for \$3.50 per ton. The Montana, however, is the better mill and has proved that fine grinding is superior to separate treatment of sands and slimes for the Tonopah ores.

Round Mountain has five small mills and one of the few hydraulic mines of Nevada. This is a prosperous camp. The Round Mountain Mining Company paid two dividends during 1908, and reported a profit of \$55,000 from working 14,000 tons of ore for the six months ending June 30, 1908.

In spite of its facilities for milling 160 tons of ore daily—present charges \$5 per ton—Manhattan made very little profit from its mines in 1908.

The town of Helena, 40 miles east of Tonopah, was started in November, 1908, on the strength of the Clifford mines, from which Goldfield option holders are shipping \$300 ore.

The Berlin mines, formerly owned by J. Phelps Stokes, of New York, have been recently bought by Goldfield operators.

The mines in the southern part of Nye county have proved disappointing. The Montgomery-Shoshone, heralded as the wonder of the world in 1906, is comparatively a failure; 17,798 tons of ore worked from January to June, 1908, yielding \$412,231, gave but little profit.

A disgraceful fiasco marked the career of the Gold Bar Mining Company, which did not find out that its ore was too low grade to work until after building a 20-stamp mill. This mill is now shut down and the property will doubtlessly be sold to satisfy the creditors of the company. Though the Homestake King Mining Company, a neighbor of the Gold Bar, is running its 25-stamp mill at present, it does not seem prosperous.

The Bonnie Clare mill is closed. The

Johnnie mill shut down in August, but is to start again soon. Judging by the complicated litigation over the stock of the Keane Wonder Mining Company, it ought to be a good property. Its 20-stamp mill is now running profitably. The Campbell-Smith custom mill near Beatty will start in February. The Skidoo mill is giving \$20,000 monthly.

The mines of Wonder, in Churchill county, shipped a little ore in 1908. The Nevada Hills mine at Fairview was not very prosperous during 1908; its ore was cut off by a fault.

Gold Circle, in Elko county, is improving and is to have a 40-ton mill.

In Humboldt county the new camp of Jessup was prominently mentioned by the newspapers. In the same county the old Hendra mine at Dun Glen was resuscitated by E. S. Chafey, after whom the new town of Chafey is named. He found a body of good ore from which he was able to pay \$30,000 for the mine by his ore shipments. These shipments stopped in November, and it is said that the mine is not looking so well. Seven Troughs, present population 1000, is likely to last for some years; for, though the fabulous riches reported a year ago have not materialized, much good ore has been developed. Twenty hoists are now running in this district, and the Mazuma Hills and the Kindergarten have each built a 10-stamp mill.

Rosebud, from which much was expected, has proved a "dead one."

Lincoln county is one of the large producers. The Bamberger De Lamar ran steadily in 1908, crushing 130,000 tons of \$4.75 ore. There is much activity in Searchlight; here the Quartette has just finished a 150-ton cyanide plant.

The famous Comstock mines in Storey county have had much newspaper notoriety lately. Pennsylvania capitalists have obtained control of some of these mines. Whether the stockholders will receive larger profits, or the mill men secure most of the product, as in former years, remains to be seen.

SILVER-LEAD

Non-argenteriferous lead and zinc ores are mined in the Good Springs district in Lincoln county, but the bulk of the lead comes from the silver-lead ores. These ores are mined all over the State, but most of them come from the Richmond-Eureka mines in Eureka county. This county produced \$400,000 in 1908, largely from silver-lead ores. At Ward, in White Pine county, the Nevada-United is shipping 20 carloads monthly of ore containing 40 per cent. lead and 6 oz. of silver per ton. In Pioche, Lincoln county, the Nevada-Utah Mining Company is reopening the famous Raymond & Ely, and the Meadow Valley mines. This camp should make a good showing in 1909.

Zinc ore is found in quantity within 35

miles of Lovelocks. The chief producers of zinc are the Potosi and the Monte Cristo mines in the Good Springs district, Lincoln county.

MINOR MINERALS

Alum.—It is proposed to work the alum deposits of Esmeralda county.

Antimony.—A small amount of antimony ore was mined. More should be extracted in 1909, since the Chase-Andrew's Company, of New York, is building a 100-ton concentrator near Lovelocks. Antimony has been mined in former years, by the Antimony King Mining Company near Austin, and also at Battle Mountain. A 12-in. vein of stibnite was found on the 120-ft. level of the Mazuma Hills mine at Seven Troughs.

Barytes.—The deposit near Silver Peak has been studied with a view of building a mill to work it.

Borax.—This is produced in small amount by Chinese lessees near Columbus, Esmeralda county.

Coal.—William Groezinger, the discoverer of the coal beds near Tonopah (these beds were first noticed in the '60s), died in November. Many old Nevadans will recognize him under the name of "Jackass Billy." He made a small fortune by giving options on his coal mines.

Gems.—A small amount of turquoise was cut from the deposits of Lincoln and Esmeralda counties. Original Bullfrog ore is used for jewelry, as is the handsome azurite and malachite mixture found at Yerington.

Gypsum.—The Arden Plaster Company has a 150-ton mill, costing \$150,000, 10 miles south of Las Vegas.

Mercury.—In former years a few flasks of mercury were distilled from the ores of Mill City, Humboldt county. For some months past Davis & Workman have made 300 to 400 lb. of mercury daily from cinnabar found at Ione, Nye county.

Mica.—A mine of this mineral has been bought, in Lincoln county, by the American Mica Company.

Molybdenum.—Occurs in many mines as wulfenite, and is found in a wide quartz vein in Lida valley, Esmeralda county, as molybdenite.

Nickel.—The American Nickel Company was to start work on its mines near Boyer, Churchill county, in November.

Petroleum.—Prospecting wells are being driven near Buckskin in Lyon county; and near Silver Peak, and south of Rhyolite in Esmeralda county, but no oil has been produced. A Government expert has reported unfavorably as to the prospects.

Platinum.—Is found in a vein in the Bunkerville district in Lincoln county, where the ore contains 3.5 per cent. copper, 2.5 per cent. nickel, and 0.25 to 0.33 oz. of platinum.

Salt.—Is made in several counties.

Sulphur.—A few loads of sulphur were

taken from a large deposit a few miles south of Goldfield.

Tungsten.—A shipment from Lovelocks netted \$120 per ton. Several veins have been worked near Round Mountain.

Ärolite.—Easy and profitable mining was the extraction of a 4500-lb. ärolite from its sandy bed in the Quinn cañon country east of Tonopah. This is thought to be the meteor that illuminated this section of Nevada and a portion of California when it fell in 1894. I understand that an offer of \$6000 has been refused for this mass of nickeliferous iron.

California

SPECIAL CORRESPONDENCE

California was credited by the division of mining and mineral resources of the United States Geological Survey with a mineral production valued at \$56,679,436 in 1907. About 40 substances are enumerated, the most important being gold, valued at \$16,853,500; petroleum, \$14,609,956; copper, \$6,739,320; stone, \$3,134,420; clay products, \$5,749,537; asphalt, \$1,213,957; borax, \$1,121,520; and silver, \$1,049,400. Other substances of lesser total value were cement, chrome, coal, glass sand, gypsum, lead, lime, magnesite, manganese, mineral waters, natural gas, ocher, platinum, precious stones, pyrite, quicksilver, salt, slate, zinc, asbestos, infusorial earth, talc, soapstone, and a few other minor substances.

Up to the end of 1907 the value of the gold output has always exceeded that of any other single substance in California; but in 1908 the value of petroleum passed that of gold insofar as the present available statistics show. The developments in the oilfields of the State exceeded in 1908 those in the goldfields. While the unit value of gold naturally remained the same, the value of the oil produced greatly increased. The estimated average value of oil in 1907 was 37c., and in 1908 it was 48c. per bbl. of 42 gal. The gain in production of oil for 1908 was about 20 per cent., whereas the gain in value was a little over 25 per cent.

There were no specially important developments in the gold-mining industry of the State in 1908. Numerous changes were made in ownership of mines; some new ones were opened and some old ones abandoned. The reopening of long-abandoned properties continued in the principal counties. Many of the old mines of the State were given up years ago because, under the circumstances then existing, they did not pay; but under modern conditions they can be made profitable when sufficient capital is invested for proper development and suitable machinery.

In general California did better in 1908 than in 1907 because there were no general

labor strikes and no floods, although the dryness in the fall affected the yield to some extent.

In the central and northern portion of the State there were no developments of note aside from a few instances. In the southern portion new railroads brought new sections into notice and gave prospectors a chance to enter regions heretofore neglected, especially in Inyo and San Bernardino counties, where numerous discoveries were made and many new mines were opened.

In the desert regions of California, particularly those bordering on the State of Nevada there was more or less activity due to the fact that, of late, transportation facilities have been provided; prospects, hitherto worthless, have since become of some value because ores can now be shipped to reduction works. For these reasons more or less prospecting was done and both old and new claims were developed to a producing stage.

In the Mother Lode section of the State and in other older portions there were few changes. Development work continued as usual. In Siskiyou and Trinity counties of northwestern California, there was much activity in gravel mining and some new quartz enterprises were begun. In Shasta county some new smelting enterprises started in 1908 so that the copper industry should show an increased output for the year. That county is the center of the copper-mining industry.

The increased output of gold for California for 1908 is expected to come mainly from the gold-dredging industry. About 10 or 12 new dredges were installed during the year; most of these are of the largest size and have double the capacity of the old-fashioned dredge. Most of them were installed in the main dredging fields on the Feather, Yuba, or American rivers, but a number were operated in localities where but a few hundred acres of available dredging ground are known to exist. Some mergers of prominent companies took place in the dredging industry.

It is expected that when the statistics of the gold-mining industry for 1908 are completed California will show an increase of \$1,000,000 to \$2,000,000 over the production of 1907. The mines were handicapped in the fall of 1908 by a dry season, and several properties were shut down for a short period. But the deficiency due to this cause will be made up by the increased output of the dredges.

The most notable feature in 1908 was the increased output and value of petroleum. It is expected that the statistics of 1908 will show that the oil yield is valued at about \$23,000,000. The Midway oil district came to the front and Coalinga displaced Kern River as the most important field. The McKittrick district increased its yield by 2400 bbl. and the Sunset district by 1000 bbl. per day. The first

three months of the year showed little increase, but the last three months gave a very large yield. With an average price for the year of 48c. per bbl. the price went up to 63c., and is expected to reach \$1 per bbl. The great demand is for a light oil, as heavy oils are abundant.

The dividends of oil companies listed on the California Stock and Oil Exchange in 1908 amounted to only \$574,556, but the total paid by them to date is \$18,008,882.

Although all the oil companies paid \$574,556 in 1908, one gold mine, the North Star, of Nevada county, paid out \$375,000. With increased prices and output, the oil companies should be more profitable.

The production of mineral substances other than gold and oil will show little change in 1908. The structural materials of the State are coming into greater demand each year, but most of the substances will show little advance in value in 1908. The high freight rates for the heavier materials restricts production inasmuch as the consumption is largely confined to the Pacific coast, and it is impossible profitably to ship them East.

The cost of producing copper at the Burrage mine in the Bathurst mining district, New South Wales, Australia, in 1907, according to *Mineral Resources*, Bulletin No. 6, issued by Department of Mines, New South Wales, was as follows: Mining, including transportation to the mill, 11s. 4.9d.; concentrating, including transfer to calciner, 5s. 2.8d.; calcining concentrates and picked ore, 1s. 4.8d.; smelting calcined concentrates and stall-roasted ore to matte, 3s. 8.5d.; roasting matte at Burrage, 1s. 1.5d.; roasting blister copper and matte at Eskbank and refining same, 1s. 8.4d.; total, £1 4s. 6.9d. per ton of ore. The ore yielded 2.36 per cent. copper; 58,159 tons were treated during the year. The high cost of mining is due mainly to the fact that the stopes dip only 25 deg. The orebody is from 10 to 40 ft. wide.

The zinc mines at Broken Hill, Rhodesia, shipped about 16,000 tons of zinc ore to Europe in spite of the high freight charges, which amounted to \$30 per ton to the seaboard, but then exhausted the high-grade zinc carbonate ore and were left with a mixture of lead carbonate and zinc carbonate and silicate, assaying about 25 per cent. lead and 25 per cent. zinc, which cannot be economically separated by any known process. There are large deposits of the ore, occurring in a limestone formation, which are nearly pure mineral, containing only a little lime as gangue, but incapable of separation into marketable products. The ore is non-argentiferous.

The United Kingdom produced 19,104 long tons of iron pyrites in 1907 as compared with 11,140 tons in 1906. Of this amount 7,394 tons came from England, 2,516 tons from Ireland and 284 tons from Wales.

Review of Mining in Foreign Countries

The Year's Developments in the Mineral Industries of the Transvaal, Peru, Chile, Colombia, Mexico, Ontario and Australia

DETAILS OF GOLD PRODUCTION

The mining industries of Canada and Mexico suffered from the same adverse conditions which affected the United States in 1908. Mexico had troubles of its own arising from the declining value of silver, so many mines in that Republic being dependent upon their silver output alone. However, Mexico is rapidly attaining a high rank as a gold producer, through the further application of the cyanide process. On this account the gold production of Mexico probably increased in 1908, and inasmuch as the gold ores yield a large amount of silver, the Mexican production of the latter metal may not show any great decline. The production of gold in South Africa was the largest on record. An increased production of gold is also to be expected from Russia.

Australasia

By F. S. MANCE*

The record of the mineral industry in Australasia during the year 1908, insofar as regards the extent to which operations were affected by the fall in the prices of the industrial metals, varies little from that of other countries. The general condition of affairs thus brought about was, however, further accentuated by a persistent decline in the gold yield. The result of the year's work, especially when compared with the buoyant returns of the preceding years, consequently makes an unfavorable showing, but a closer analysis of the position makes it appear that the magnitude and extent of the operations conducted under such disadvantageous circumstances afford good grounds for satisfaction, and tend to emphasize the possibilities which, under favorable conditions, are yet likely to eventuate from the development of the mineral resources of this country.

GOLD

The gold production of Australia has for some years past shown a steady decrease, and although the falling off during the year 1908 was not so pronounced as in previous years, still the forecast indicates that a decline of about 65,000 oz fine may be looked for, or a decrease of 1.8 per cent. on the production for the year 1907.

The following comparative statement

shows the yield for the last two years, the figures for 1908 being estimated on the basis of the production for the first ten months of that year:

	Yield 1907, Oz. Fine.	Yield 1908, Oz. Fine.
Western Australia . . .	1,697,554	1,662,300
Victoria . . .	695,376	681,400
Queensland . . .	465,882	463,500
New South Wales . . .	247,393	230,000
Tasmania . . .	65,355	62,500
South Australia and Northern Territory . .	10,651	9,000
Commonwealth . . .	3,182,381	3,111,900
New Zealand . . .	477,312	482,500
Australasia . . .	3,659,693	3,594,400
Value . . .	\$75,645,854	\$74,296,248
Decrease . . .		\$1,349,606

The position will be more clearly gaged when it is stated that the estimated production for 1908 represents a decrease of 15 per cent. on that for the year 1903, the decline from this latter year having been constant.

The State of Western Australia contributed 53 per cent. of the production of the commonwealth during the year 1908, and the indications are such as to favor the opinion that the output has reached a normal level, and that there is not likely to be a further continuation of the decline which has characterized the yield for some years past. Some of the outside fields certainly give evidence of partial exhaustion, but as against this the developments at the deep levels in the mines at Kalgoorlie, and the systematic manner in which operations are proceeding, strongly support the view to which expression has just been given. The dividends paid by mining companies in this state during the first ten months of the year totaled \$6,121,000.

The industry in Victoria cannot be viewed with equal complacency, and the gold yield for 1908 promises to be the lowest for the past 15 years. The falling off is principally due to the closing down of one after another of the deep alluvial mines, owing to the exhaustion of the deposits. The efforts made to prove the extension of these leads have involved the expenditure of very considerable sums during recent years, but so far without any measure of success. The lower grade of the ore which is being won as depth is attained on the Ballarat and Bendigo fields, the increased cost of working, and the consequent lessening of the margin between profit and loss, are all adverse

factors. As illustrating the depth to which operations have extended, it may be mentioned that the Victoria quartz mine at Bendigo has opened up a reef 4 ft. wide at a depth of 4504 ft. from the surface.

In the state of Queensland the depression of the preceding year has not in any way lifted. The government has endeavored to stimulate operations by voting a substantial sum for the purpose of carrying out deeper sinking and prospecting, and has also undertaken the construction of railways to connect the outlying mines. However, the success which has attended the operations of the Mount Morgan company, and which is referred to later on under the heading of "Copper," is a particularly pleasing feature of an otherwise disappointing year.

In New South Wales there were no developments of significance during the year, and the yield was mainly contributed by the established mines on the Cobar and Wyalong fields, and by the dredging plants. Here, as in the other eastern states, the waning productiveness of the gold mines and the absence of any developments which are likely to arrest the decadence, are matters for much concern when the future of the industry comes to be regarded.

The production of the states of Tasmania and South Australia was unfavorably influenced by the lessened output of those metals with which the gold in small quantity is found associated.

The yield of the Dominion of New Zealand, as disclosed by the returns for the first ten months of the year, gives every indication of showing a substantial gain. This is due to the increased output by the mines in the Ohinemuri district, which include the famous Waihi mine. This mine has been creating fresh records with each succeeding crushing, and the results have given a gratifying impetus to operations on the Thames field. The dredges at Otago and the West Coast, which have been important contributors in the past, furnished a lessened output during the year under review.

SILVER-LEAD

The serious fall in the prices of these metals resulted in a complete dislocation of the affairs of the companies on the Broken Hill field. Events show that the sharp decline which took place early in the year was not anticipated, and the companies were thus unable to adjust

*Department of Mines, Sydney, N. S. W.

their internal economies in time to lessen the severity of the effects of the falling market. The companies were further handicapped by the fact that the agreement made with the miners when lead was at a top price, allowing a 12½-per cent. increase in wages, did not terminate until the end of the year, while the new customs' tariff had added considerably to the cost of supplies. The results are reflected in the report of the Broken Hill Proprietary Company for the half-year ending May, as, although the production was considerably greater, the profit for this term amounted to only \$110,919, as against \$1,501,119 for the same period in 1907, and for the first time in the company's history the declaration of the quarterly dividend had to be deferred. Several of the mines closed down, others worked fewer shifts, while development work was almost wholly discontinued, so that the number of men employed at the end of September was 6009, which shows a decrease of 50 per cent. compared with the same date in 1907. The position of affairs on the field at the time when this article was written was very unsettled, as the miners were making a determined stand against any lowering of wages, and had made a demand for the reduction of the hours of labor to 44 a week.

The output of metals was fairly well maintained, and for the financial year ending May the Broken Hill Proprietary Company raised 592,362 tons of ore and produced 74,575 tons lead, 5,315,314 oz. silver, and 1,955 oz. gold. The difficulties which some of the companies experienced in respect to the high, returning charges on their concentrates sold to foreign buyers seem likely to be settled at an early date, as the Broken Hill South and the North Broken Hill companies secured an option of purchase over the Australian Smelting Company's Works at Port Kembla (N. S. W.).

The effect of the fall in the prices of the metals on the silver-lead mines of New South Wales, generally, is more fully disclosed by the returns of the exports from this state for the first nine months of the year, as the value of the silver-lead concentrates, etc., despatched totaled \$9,320,844, or \$4,158,152 less than for the same period in 1907.

In Tasmania the output from the mines at Zeehan and elsewhere was greatly restricted owing to the closing down in April of the Tasmanian Smelting Company on account of financial difficulties. The government purposes to come to the financial assistance of the company with a loan of £20,000, and it is expected that, if this be done, supplies of ore can be obtained which will enable a fair margin of profit to be realized under present conditions.

In Queensland a satisfactory increase is recorded both in the quantity and value

of the silver-lead production, the output for the nine months of this year being 730,465 oz. silver and 4712 tons lead. This yield was furnished mainly by the Chillagoe Mining Company, the chief supplies of ore being drawn from the Mungana Company's Girofla and Lady Jane mines.

ZINC

Under this heading it is pleasing to be able to record that the year witnessed satisfactory progress in respect to the operations of the several companies on the Broken Hill field. The Proprietary company's experimental spelter furnace proved so successful in actual work that the erection of nine additional furnaces was put in hand, to be completed and in operation by January, 1910. It is estimated that these furnaces will be capable of producing 8000 tons of spelter per annum,

plant was not worked full time at the close of the year.

The output of the De Bavay Company was almost doubled without any addition to the plant, the working costs were materially reduced, and a high rate of extraction was secured.

The other processes seem also to have made forward strides, but it is noticeable that those engaged in the chemical treatment of the tailings show an exceptionally high recovery when compared with mill plants, while even in mechanical details a great many advantages are apparent.

COPPER

The commonwealth statistician reports that the value of the copper exported from Australia during the first nine months of 1908 totaled only \$7,806,000, as compared with \$13,720,000 for the same period in

PRODUCTION OF MOUNT LYELL COMPANY.

Year Ending September.	Ore Treated, Tons.	METAL PRODUCED.			Dividends Paid
		Copper, Tons.	Gold, Oz.	Silver, Oz.	
1905	412,273	8,203	24,290	739,691	\$730,500
1906	394,752	9,009	23,088	703,945	1,314,900 }
1907	406,397	7,886	19,449	700,087	1,972,350 }
1908	401,983	8,611	19,532	681,262	1,095,750 }
	1,615,405	33,739	86,359	2,824,985	\$5,113,500 }

and that there is sufficient raw material on hand at present to keep them supplied for 38 years. The zinc concentrating plant of this company is at present producing at the rate of 76,000 tons of concentrates per annum averaging about 45 per cent. zinc.

The Zinc Corporation, Ltd., formed to treat the enormous heaps of accumulated tailings on the Broken Hill field, after many reverses and set-backs, also appears to have now brought operations to a successful issue. The Elmore plant, which was adopted, is stated to be doing all that was claimed for it, and high recoveries of both zinc and lead are reported. The company is at present working on a good dump of tailings purchased from the Block to company. The average quantity of tailings now treated monthly approximates 16,000 tons, yielding 5840 tons zinc concentrates and 410 tons lead concentrates, the assay values being: zinc concentrates, 46.5 per cent. zinc, 16.5 oz. silver, 7.4 per cent. lead; lead concentrates, 56 per cent. lead, 38.5 oz. silver, and 17 per cent. zinc. It will be interesting to see if this extraction can be maintained when the heaps of inferior tailings come to be handled.

The Potter process in use at the Squibb Corporation's mine is stated to be securing an extraction of 90 per cent., and about 1200 tons of tailings per day are treated, the product assaying 40 per cent. zinc. A difficulty is experienced in finding a market for the concentrates, and the

1907. In the face of these figures the results secured by the Mount Lyell Company, Tasmania, as set out in the accompanying table, make a pleasing showing.

The 850-ft. level in the North Mount Lyell mine is now one of the principal sources of the ore supply. The development work undertaken at the 1000-ft. level gave particularly satisfactory results, the orebody being proved to be of considerable size, and to maintain fully its value. The accession to the ore reserves during the last half-year in this mine amounted to 169,000 tons, or 103,000 tons in excess of the output. The Mount Lyell open cut, as hitherto, supplied the pyrites for smelting purposes, and for acid making. It will be noted that the ore treated during 1908 was of a higher grade than during the preceding term, and is consequently responsible for the increased production of metals. As further evidence of the healthy position of this company it may be mentioned that the cost of producing blister copper during the last half-year was only \$3.4 per ton of ore treated.

In South Australia, the Wallaroo & Moonta Smelting Company found it necessary considerably to modify the program of operations, and as a result it is anticipated that the production of copper from the company's mines during 1908 will reach only some 5300 tons, or 1700 tons less than for the previous year. Purchased ores are estimated to have furnished an additional 300 tons as against 1720 tons in 1907. The cost of produc-

ing fine copper per ton was considerably lowered, and is approximately as follows: Mining, \$180; smelting, \$66; shipping, \$261, and other charges, \$6; total, \$522. The ore dealt with during the year is estimated at 105,000 tons. Development work was undertaken on a scale fully commensurate with the extent of ore raising, and the area of new ground opened up by the exploratory work, as a whole, showed no variation in its average value. The increasing depth of the workings necessarily tends to an advance in costs, but taken all in all the prospects must be regarded, under similar conditions, as decidedly favorable to a maintenance of the results of the present year.

In the state of New South Wales several of the mines which have been important producers in the past were closed down either wholly or in part during the year, and the value of the copper exported during the first nine months of the year amounted to \$2,131,000, or \$1,365,000 less than for the same term in the preceding year. The Great Cobar, Ltd., maintained its position as the largest producer in this state, and during the year the company completed the extensive additions to its plant, which have been in progress for some time, and carried out a large amount of development work. The lode at the 1000-ft. level has been found to improve in width, while its value exhibits no alteration. In these circumstances the returns for the year may be expected to show a well augmented production, and a higher extraction combined with economies in working costs. Of the other smaller mines, that owned by the Grafton Copper Company at Cangai probably yielded the most satisfactory results.

While the state of Queensland naturally experienced a great reaction after the copper boom, still the attention which it was the means of directing to the important deposits of this state was productive of good results and proof of this is afforded by the output for the first nine months of 1908, which was 10,508 tons of copper, as against 9,462 tons for the same months in the previous year. The Mount Morgan mine quickly gained the pride of place as the chief contributor of this state. The following statement of the production of gold and copper shows the strides made during the course of the last three financial years:

OPERATIONS OF THE MOUNT MORGAN MINE.

Year Ending May.	Gold, Oz.	Copper, Tons.
1906	117,197	483
1907	145,138	4,087
1908	153,091	5,561

The oxidized ore in the surface levels is rapidly becoming exhausted, but the supply of mundic ore from the inter-

mediate levels is well maintained, while development work underground has revealed the existence of larger quantities of auriferous copper ore than previously estimated by diamond drilling, the average value of that so far mined being 3.30 per cent. copper and 8.62 dwt. gold per ton. The present reduction plant is capable of dealing with 216,000 tons of this ore per annum. In the latter months of the year several extensive falls of earth occurred at the 750-ft. and 850-ft. levels, and which, unhappily, were responsible for the death of 12 men. Operations were retarded on this account, and a special board was appointed by the government to advise as to the method of conducting future operations, the present system of "pigsties" being shown to be unsafe.

At the O. K. mine the stopes in the various levels opened out well, and the ore reserves were considerably augmented. Toward the close of the year this mine contributed an output of about 140 tons of blister copper per month. The Chillagoe Mining Company maintained a satisfactory output, the chief supplies of copper ore being drawn from Ruddygore and Redcap. Important contributions were also furnished by the mines at Mount Perry, and those on the Cloncurry field.

The works of the Electrolytic Refining and Smelting Company at Port Kenbla were completed and got into working order in the month of December. This company has contracts with the Mount Morgan and other mining companies for the supplies of matte, and Australia is now in a position to enter the lists as a large supplier of electrolytic copper.

TIN

Under this heading there are few developments of note to record. The industry received a set-back owing to the lower prices ruling, the extent of which is apparent when it is said that the value of the exports from the commonwealth during the first nine months of 1908 was \$3,091,000, as against \$4,428,000 for the same period in the previous year.

The Mount Bischoff Company, Tasmania, continued operations uninterruptedly, the several fresh bodies of high-grade ore opened up having proved of material benefit at a period which was regarded as a critical one in the company's history. The usual dividends were accordingly regularly declared, and the sum distributed to shareholders by this company now totals \$10,400,000.

The mines in the Derby district, including the Briscoe and New Brothers Home, in the circumstances, experienced a fairly satisfactory year, and contributed about 1500 tons of tin oxide; the future prospects, however, indicate a reduction in the output. The production of tin ore from the state of Tasmania for the first

three-quarters of this year is valued at \$1,514,000, as compared with \$1,920,000 in 1907.

In New South Wales the alluvial deposits in the Tingha and Emmaville districts continue to be systematically worked, the operations of the dredges, although somewhat hampered by an insufficient rainfall, proving fairly satisfactory. Several small, but rich, lodes were also worked. The exports of tin from this state during the nine months, however, reached only a value of \$1,225,000, or \$1,050,000 below that for the same term in 1907.

In Queensland the output was much on the same scale as in the preceding year, the production to the end of September reaching 3914 tons, or within 51 tons of the output for the first nine months of 1907. The value, however, shows a drop of over \$600,000. The Walsh & Tinaroo field is still the chief center of operations, but the general results do not come up to those of last year, owing to the fact that two of the large producing mines, the Smith's Creek and Stannary Hills, suspended operations pending reconstruction of the companies. The position was somewhat relieved by the opening up of rich ore in the Vulcan mine, and the lode in this mine has now been proved to a depth of 1400 ft. The Great Northern Freehold mine at Herberton is also contributing improved returns, while the dredging industry at Stanthorpe has made good headway.

Of the tin fields in the Northern Territory little was heard during the year. Operations at the Pilbarra and Greenbushes fields in Western Australia were also unfavorably influenced by market conditions.

OTHER METALS

Mining for tungsten was adversely affected by the fluctuation in market values. The government geologist of Queensland estimated that the wolfram-bearing country of the Walsh & Tinaroo, and the Hodgkinson fields, extends over an area of 3500 square miles. Operations there were proceeding on an increasing and promising scale, as shown by the fact that during the first three-quarters of 1907 the quantity of wolfram produced by this state totaled 505 tons, but during the corresponding term this year the production, owing to the closing down of the mines, fell to 225 tons.

In New South Wales the mines at Torrington also suspended work for several months during the year.

Iron smelting now appears to have been established on a permanent basis at Lithgow (N. S. W.), the iron and steel produced being in every way satisfactory. The Federal Government, with the object of encouraging the industry, passed a bill through the House of Representatives granting a bonus of \$2.88 per ton on all

pig iron made from Australian ore, also on puddled bar iron and steel made from Australian pig iron. The total sum set apart for the purpose is \$730,500, and the annual bounty is limited to \$146,100.

COAL

The labor troubles which seriously threatened this branch of the industry in New South Wales in the early part of the year were happily averted, and the output promises to be one of the largest in the history of the state, that is if the figures of the export trade may be taken as a guide. These show that the coal exported during the nine months of the year reached a total of 4,686,553 tons and was valued at \$11,304,975, showing an increase of 461,000 tons and \$1,865,658 in value compared with the same months in 1907. The coal trade generally was exceedingly brisk during the first half of the year, after which there was a noticeable slackening off. The coke trade, while feeling the effects of the depression in metalliferous mining, was, on the whole, satisfactory.

South America

BY JOHN POWER HUTCHINS*

The year 1908 was not a prosperous one for South America. Countries like Peru, Bolivia and Chile, which produce copper, silver, lead and other metals felt the hard times particularly and production suffered. The gold-producing countries were not affected. Colombia, Brazil and the Guianas about maintained their production. Ecuador is a gold producer but of inconsiderable importance.

Peru will show a larger copper production, for the Cerro de Pasco smelter operated continuously and produced about 30,000,000 lb. of copper. Silver mining suffered greatly and many of the mines are shut down. Gold mining, both placer and lode, was actively conducted in southern Peru. The extensive coal deposits are being investigated with good results and there is a likelihood of extensive developments. The coal is bituminous and coking. The coal deposits of Chile are nearly exhausted, while no coal has yet been developed in Bolivia. Peruvian coal is, therefore, in greater demand than formerly.

The Chilean copper mines generally continued operation but no new enterprises were started because of the low price of the metal, and the low exchange. Considerable interest has been taken in concentrating low-grade copper ores.

Bolivia still suffers from high cost of transportation.

*Mining engineer, 52 Broadway, New York.

GOLD

The total gold productions of some of the countries of South America in historic times is remarkable. Colombia is credited with \$895,000,000; Brazil, \$720,000,000; Bolivia, \$199,000,000; Peru, \$119,000,000; Chile, \$33,000,000. This makes a grand total of nearly \$2,000,000,000. These figures suggest possibilities for further development and exploitation with modern methods particularly in placer mining. In South America, as in all partially developed regions, the more important mines are the placers, and nearly all the past and most of the present production is from alluvial deposits. Many of these placers are essentially one-man enterprises, but there are others which could be worked on a large scale by dredger or hydraulicking.

Gold mining in Colombia has an interesting history. Its deposits were worked by the Spaniards with slave labor soon after the discovery of America, and in 1905, with \$805,000,000, it still ranked fourth in total gold production of the world, only the United States, Australasia, Russia and Siberia outranking it. Compare the area of Colombia with those of the three regions that outrank it; then remember that most of the gold produced by Colombia came from a comparatively small part of the total area.

A very large territory in South America lies awaiting prospecting and development. There are several reasons why this area has not as yet been investigated. All of the tropical parts of the continent have at low altitudes a climate with a pernicious effect upon the health of the white man of temperate zones. His efficiency is lowered soon after arrival and usually he cannot stay in the interior for a year without a trip to the coast or the sea, or a visit to higher altitudes to recover from malaria and anaemia. Nor does a residence of several years in the tropics with vacations to healthful climate, give much, if any, immunity from malaria. A person hardened in that way may be ill less frequently than the newcomer in the tropics only because he knows how to take care of himself. Those parts of South America which lie at elevations more than 3000 ft. or in the temperate zone have no difficulty with malaria.

Lode mining is carried on in Peru, Colombia, Ecuador, British Guiana, Brazil, Venezuela, Chile, Uruguay, Argentine and Bolivia.

Colombia has a few profitable gold-lode mines. The most important of these are the Frontino and Bolivia near Remedios in the department of Antioquia. An intensive investigation of lodes has been carried on in southwestern Colombia for several years by Americans. Several promising properties are under development in this region near the boundary

line of Ecuador. Difficult transportation has been and will continue to be a serious obstacle.

Lode mining is carried on in Ecuador only in the Zaruma district, where the application of the cyanide process has made it possible to do profitable mining. A small amount of placer gold is produced on the headwaters of the Amazon river in Ecuador.

This is an extremely inaccessible region and will probably remain undeveloped for many years.

OTHER MINERALS

The nitrate deposits of Peru, Chile and Bolivia were worked as usual.

The extensive asphalt deposits of Venezuela are not worked, although the product is of high grade. There are several good reasons for this lack of activity. The limited demand is easily supplied from the more accessible though less pure deposits at La Brea on the coast of Trinidad, and the government of Venezuela has hitherto been far from stable.

Mexico

BY H. A. HORSFALL*

Mining in Mexico during 1908 showed very erratic conditions. The first of the year opened with extreme depression, owing primarily to the financial panic in October of the preceding year; in the early months of the year a considerable recovery was noticed in the prevailing conditions, which was succeeded by successive periods of advance. Toward the latter part of the year, however, depressed conditions were reported and they still prevail.

The reduced prices of the various metals was the chief and primary cause of the continued depression. Copper and lead prices, however, materially advanced since the middle of the year, but silver, of which Mexico is the largest producer, continued to recede in price during the whole of the year, until at the present market price very few mines are able to show a working profit. Other matters tending to aid in the depression were the agitation of material changes in the mining laws, increased railroad freight rates on coal, ores and iron and steel products.

These conditions continue operative at the conclusion of the year, except the uncertainty in regard to the mining law. A number of large deals, which had been pending for some time were lately reported as consummated; others owing to the prevailing money conditions have been held up indefinitely. On the whole a considerable advance as compared with the preceding year was accomplished.

*Mining and mechanical engineer, New York.

GOLD AND SILVER

The gold output continued to increase at a rapid rate, notably in the districts of Guanajuato, El Oro and Dolores, as reported in previous years. The increase is partly due to the discovery of new mines, but principally to the increased use and continued improvement of the cyanide process for treating gold and silver ores. A large number of new mills using this process were put into commission during the year. Notwithstanding the general adverse conditions prevailing, the quantity of silver produced will show a material increase over previous years, new producers having come to the front and the old ones having increased their output. In prospecting greater attention was given to gold properties and many promising prospects were located.

COPPER

The complete cessation of operations at the Cananea mines at the close of the previous year was followed by the complete reconstruction of the smelting plant, and partial resumption of production, since July. The Bolco company operating in Lower California will probably lead in the amount of copper produced during the twelve months, followed by the mines at Cananea.

The starting of the 2000-ton concentrating plant at Nacozari, several new copper smelters in various parts of the country, and additions to the capacity of the older plants, will in all probability, give an increase in production in 1909.

LEAD

Notable additions to the amount of lead-silver ores produced were reported, particularly in the districts of Mapimi in the state of Durango, and Santa Eulalia in the state of Chihuahua. This is to be discounted, however, by the decreased production from the silver-lead mines of the Sierra Mojada district; late reports from this district indicate that many of the mines have resumed shipments. On the whole the production of lead will be about the same as in previous years.

TIN

A number of tin properties in the state of Aguascalientes are reported to have been purchased by Americans and are being developed. Deposits of tin ore were discovered in the state of Coahuila, near the Rio Grande river opposite Boquillo, Texas. The owners are said to contemplate extensive developments.

MERCURY

A number of properties producing quicksilver were in operation during 1908, high prices being the cause. Extensive deposits are known to exist in several

states; many of them were formerly worked.

IRON AND STEEL

Very little progress in the utilization of Mexico's resources in the manufacture of iron and steel was reported. The Monterey Iron and Steel Company has, however, been able to start up its steel plant on a large order for rails for the Mexican National railroad. The plant at the city of Durango, it is rumored, will start up again in a very short time. The manufacture of iron and steel showed very little advance in consequence of the continued shortage in the necessary fuel requirements. The recent opening of a branch of the Mexican Central railroad, from Guadalajara to the gulf coast, will in all probability, lead to increased activity in this branch of mining, for new discoveries of coal and iron ore are reported from that section.

COAL AND OIL

Coal mines in the state of Coahuila continued to produce their normal output. Reports of discoveries in other states were received, from time to time, but as yet the production has been on a limited scale. Prospecting for oil in the state of Vera Cruz was very active during the past year. The firm of S. Pearson & Son placed in operation the new refinery capable of producing 6000 bbl. per day. Prospecting in Chihuahua by the Hearst syndicate has been stopped temporarily.

OTHER MINERALS

Other mineral products of importance produced in Mexico are: antimony, sulphur, asphalt, salt, building stone, onyx of Puebla, and precious stones, of which the most important are opals and turquoise. Late reports from the statistical department of the Mexican government give the amount of Mexican and foreign capital invested in the mines and industries of that country as follows: Mexican capital, 475,509,468 pesos; American, \$336,091,000; English, £52,169,717; German, 109,817,500 marks; French, 83,757,500 francs; Austro-Hungarian, 1,000,000 florins; Spanish, 12,334,300 pesetas, and Italian, 300,000 liras.

RAILROAD BUILDING

The increase of new railroad mileage, during the year was confined principally to the states of Sonora and Sinaloa. In Sonora the branch from Nogales, Ariz., to Cananea was completed and placed in operation on Dec. 15. On July 28, 354 kilometers from Navajo, Sonora, south to Culiacan, Sinaloa, was placed in operation. At the present time the rails have been laid to Mazatlan on the coast and 31 kilometers from Culiacan south

to the Lorenzo river will be open for traffic Jan. 15, 1909.

In the state of Jalisco the Mexican Central completed and opened for traffic its branch from Guadalajara to Colima, and is building in the state of Durango, from its present terminus at Rosario, south to Inde. The Parral & Durango railroad is making additions in the state of Chihuahua and has let a contract for an extension southward from its present terminus into the mountains of Durango. Other small additions were made during the year. The Southern Pacific is building northward from Guadalajara toward the coast and recently put in operation 34 kilometers from Orendain station on the Mexican Central to Tequila, Jalisco.

CHIHUAHUA

This state ranks among the first in the number of new enterprises started during the year under review. Some of the old producers ceased operations, but new ones have arisen to replace them. The principal production, as in former years, came from the districts of Parral and Santa Eulalia. The Lluvia de Oro in the southwestern part of the state is closed down during the reconstruction of the milling plant; it produced some gold during the year. The Dolores mines continued to increase their gold production. The Rio Elata Mining Company operating at Santa Barbara in the southwestern part of the state showed a large increase of production. The Cienega gold mine, a short distance south of Morris in the district of Rayon is said to have taken out with arrastres \$12,000 in gold in a period of nine days. This mine has been worked for only a year. A number of promising gold prospects were recently located in the extreme southwest part of the state.

The Republica mine was a steady producer. The mines at Candamena are producing 20,000 oz. of silver per month. The Palmilla mine is again listed among the producers. The Watterson Gold Mining Company, Ltd., is still a constant producer. The Batopilas mines furnished their usual quota of silver. Numerous other properties are developing and sending out small shipments. The mines at Yoquiva are again working. The Reina mine near Cusihuriachic, formerly a bonanza, again started working.

The district to the east of the city of Chihuahua, along the line of the Kansas City, Mexico & Orient railroad is having a boom, and quantities of zinc ores are shipped to smelters in the United States. The gold mines at Guadalupe, formerly large producers, are being reopened. Nearly all the large properties at Parral were recently shut down. The Chihuahua smelter has three stacks in operation, and is shipping a car of lead bullion daily.

COAHUILA

Activity in zinc properties was marked during the year. The coal mines produce their usual quota. The silver-lead mines of the Sierra Mojada district are reported to be shipping an aggregate of 8000 tons per month after a long period of comparative idleness. The several smelting plants situated in this state were in continuous operation during the year.

DURANGO

The various mining camps in this state showed a very considerable amount of activity during the year and I have no doubt that the production of metallic products will show a material increase as compared with that of the preceding year. The mines in the district of Guanaecvi shipped 2000 tons of ore to the smelters, and bullion and zinc precipitates to the amount of about 68,000 pesos monthly. The most active mines in the Topia district are: San Jose de los Llanitos, La Portilla, Cardena and San Ramon. In the Mapimi district the producing mines are: Ojuela, owned by the Penoles Mining Company, San Jose; El Suerte, and several others. The Boca del Cobre mines in the Nazas district were large shippers of ore to smelters. The Promontorio mine in the Papasquiario district is in operation. In the Tamazula district the Fernando Mining Company continued working during the year. The Las Reyes mine is reported to have been sold. The survey for the extension of the Durango & Sinaloa railroad, from Culiacan was completed to this district. A large number of mines in several districts are about to resume operations while many properties in various parts of the state were in process of development during the year.

GUANAJUATO

The various mines composing this camp showed increased activity during the year. At present it has a combined monthly production of more than 70,000 tons of ore with an approximate value of \$1,500,000. The principal producing companies in the Guanajuato camp are: the Guanajuato Reduction and Mines Company; Perigrina Mining and Milling Company; Guanajuato Amalgamated Gold Mines Company; Guanajuato Consolidated Mining and Milling Company; Pingüico Mines Company; San Matias Mining and Milling Company; El Cuho Mining and Milling Company; Guanajuato Development Company; Mexican Milling and Transportation Company, operating the San Prospero and Naya groups; and the Santa Natalia Mining Company. Other companies are developing mines and shipping ores to smelters. At Peñon Blanco the Benito Juarez Mining Com-

pany completed and placed in operation at the close of the year, a 200-ton cyanide plant. At Jesus Maria the Amalgamated Gold Mining Company completed the foundations for a mill; at San Felipe the Providencia San Juan de la Luz is shipping high-grade ores and continues to be a large dividend payer. Other mines in various parts of the state are making shipments.

GUERRERO

The mining interests in this state, on the west coast, are still suffering from lack of transportation facilities. Guerrero, however, continued to produce a large quantity of silver, the Campo Morado district production alone being estimated at 300,000 pesos per month. The Socavon del Rey, La Borda, and La Conquistadora mines in the Taxco district are reported to be in bonanza. Considerable zinc is produced and a number of mills are under construction. General conditions are, however, in a state of depression owing to the low price of silver.

HIDALGO

The usual production from the great mines of this state continued. The districts of Pachuca, Zimapan, and Real del Monte are reported as fairly prosperous. The new mill of the Real del Monte of which the United States Smelting, Refining and Mining Company is the principal owner, is ready for operation. The Santa Gertrudis Company produces approximately two and one-half millions of pesos annually. The San Rafael is another large producer. The Blaisdell Coscotelan Syndicate 500-ton tailings mill is ready for operation.

JALISCO

Mining in this state continued to show increasing activity during the year. Several new mills were placed in commission, and many mines increased their shipments to the smelters. The opening to traffic of 34 kilometers of new railroad by the Southern Pacific was announced on Dec. 10. The completed portion extends from Orendain on the Mexican Central to Tequila. An additional section is promised by March, 1909. Trains are now running on the Manzanillo branch of the Mexican Central from Guadalajara to Colima. Lignite of good quality has been discovered at Zapotiltic on the Mexican Central.

MEXICO

Much activity was reported from the vicinity of Toluca, principally in the districts of Sultepec, Temascaltepec, and Taxco. In Zacualpan, the Alacran, Carboncillo, and Seguridad mines are in bonanza. In the El Oro district, the El Oro Mining and Railway Company, Ltd. treated a large amount of ore with good

results. The Esperanza mine opened up ore of high value and production continued to increase. The combined value of the product of the El Oro Mining and Railway Company, the Mexican mines and La Esperanza, for the first six months of 1908 was 9,285,782 pesos.

MICHOACAN

The El Oro district lies partly in this state. The Dos Estrellas in this district is the largest producer. The Ocotes Mining and Milling Company is developing property in the Talpujahua district. There are several other properties which ship to the smelters.

OAXACA

The principal mining camps of this state maintained a fair production. The principal districts in the order of their importance, are Taviche, Sierra Juarez, Ocotlan and Ejutlan. Oil was found by prospectors south of Ejutlan, near the coast. A number of milling plants are in process of erection.

SAN LUIS POTOSI

Increased activity in the zinc-silver industry was noted. The production of sulphur now amounts to 2000 tons per month, which is exported to foreign countries from the port of Tampico. Exploration for oil in the Huasteca country was continued. The Tiro General mine at Charcas shipped 400 tons of ore per month to the smelters at Aguascalientes during the early portion of the year.

SINALOA

The government reports 51 mines as working during the year with a production approximating six million pesos. Railroad building was active. Many new mining projects were started.

SONORA

Notwithstanding the general depression prevailing in the financial world, mining in this state showed a marked advancement during the year. Among the many notable achievements of the last 12 months are: The completion and placing in commission of the 2000-ton concentrating plant at Nacozari. The smelter at Fundicion, in the Alamos district, commenced operation in June. The completion of improvements and the partial resumption of smelting at the works of the Greene-Cananea company was another event of the year. Many new properties were under development, while the old producing silver and gold properties maintained, and in some instances exceeded their previous production. In the southern and central portions of the state a scarcity of labor prevailed. Railroad building was actively prosecuted, some new mileage was opened to traffic, and more is promised for the early

months of 1909. More attention was paid to prospecting for gold mines than in previous years.

ZACATECAS

In this state the mining industry passed through a period of extreme depression. The El Bote mine has rich ore; the Bohemia mines at Sombereete are in bonanza, and other properties are developing. The Magistral smelter with a capacity of 300 tons per day was put in operation during the year. A railroad is building from Gutierrez station on the Mexican Central to Sombereete.

TERRITORY OF TEPIC

There are a number of mines, in this territory, the property of Americans, but most of them are as yet in the development stage. Since July, prospecting was reported to be very active, particularly in the western part of the province near the line of the proposed new railroad now being built by the Southern Pacific. The producing mines in the territory are those of the Buenavista Company; those of the Castellana Consolidated Mining Company, operating the Certuchena, Rondanera Soledad and others; San Jose de Ventanas, Santa Fe, La Libertad, El Macho Rucio, Ventanas, Pinadillo, La Mexicana, Palmera, Mina del Monte and Zopilote. The San Miguel and Zapotan mines are not producing at present.

The Transvaal

By W. FISCHER WILKINSON*

During the year 1908, the mining industry of the Transvaal expanded considerably, both as regards gross production and profits. Several new mines commenced crushing and many producing companies increased during the year their reduction plant and output. Comparing the month of September, 1908, with December, 1907, there was a net increase of 242 stamps in the Witwatersrand district. The tonnage crushed per stamp was considerably increased due to increased weight and to the assistance given by tube mills. The statistics for these two months are given in an accompanying table:

INCREASE OF MILLING IN THE WITWATERSRAND				
	Stamps at Work.	Tons Milled.	Tube Mills.	Tons per Stamp Month.
Dec., 1907	8,383	1,349,580	67	161
Sept., 1908	8,625	1,534,755	102	178

The new companies contributing to this increase were the Aurora West United with 60 stamps, and the West Rand Consolidated Mines with 80 stamps, both of which companies made their first return

during September. Of the old companies the Ferreira Deep added during the year 40 stamps to its reduction plant; the Durban-Roodepoort Deep, 40 stamps; and the New Kleinfontein, 20 stamps.

In October, the production was still further increased by the entry into the list of producing mines of the Jupiter and Simmer Deep, which have a joint 300-stamp mill, and of the Cinderella Deep, which has a 50-stamp mill. In November, the Geduld company, which also has a mill of 50 stamps, made its first return. At the end of the year there will probably be about 9000 stamps dropping in the Witwatersrand district.

PRODUCTION

Adding the estimated production of the outside mines, the total gold production of the Transvaal for 1908 will have in round figures a value of £30,000,000, which is, of course, a record production and represents 35 per cent. of the world's gold production, assuming that other countries maintain the production they made in 1907. The accompanying table,

TRANSVAAL GOLD PRODUCTION.					
Year.	WITWATERSRAND DISTRICT.			Outside Mines Value.	Transvaal Total.
	Tons Milled.	Value.	Value Per Ton Milled, s.		
1884-9	1,000,000	£2,440,000	48 83	£238,231	£2,678,231
1890	730,000	1,735,491	47 4	134,154	1,869,645
1891	1,154,144	2,556,328	44 2	367,977	2,924,305
1892	1,079,354	4,297,610	43 4	243,461	4,541,071
1893	2,203,794	5,187,206	47 0	293,292	5,480,498
1894	2,890,885	6,963,100	49 2	704,052	7,667,152
1895	3,456,575	7,840,770	45 2	728,776	8,569,555
1896	4,011,697	7,864,341	39 2	739,480	8,603,821
1897	5,325,355	10,583,616	39 74	1,070,109	11,653,725
1898	7,324,446	15,141,376	41 3	1,099,254	16,240,630
1899	6,872,750	15,067,473	48 84	661,220	15,728,693
1900	459,018	1,510,131	65 82	1,510,131	1,510,131
1901	412,006	1,014,687	49 25	81,364	1,096,051
1902	3,416,813	7,179,074	42 00	74,591	7,253,665
1903	6,105,016	12,146,307	39 79	442,941	12,589,248
1904	8,058,295	15,539,219	38 46	515,590	16,054,809
1905	11,160,422	19,991,638	35 82	810,416	20,802,074
1906	13,571,554	23,615,400	34 8	964,587	24,579,987
1907	15,523,229	26,421,837	34 04	981,901	27,403,738
1908*	18,000,000	28,750,000	31 8	1,210,000	29,960,000

*The December figures are estimated by O'neil to the practice on some mines of keeping large gold reserves, which may not have been declared in December, it is not possible to make a close estimate. The gold reserves at the end of November were about 118,000 oz. of a value of £500,000.

compiled from the returns of the Chamber of Mines, shows the gold production of the Transvaal from 1884 to 1908:

Large as the figures for 1908 are, a further expansion in the early months of 1909 may be confidently awaited, as there are several companies with reduction plants in course of construction. Among these may be mentioned the Knights Central, which will start with a mill of 100 stamps, the Vogelstruis Consolidated Deep with a mill of 40 stamps, and the Bantjes with 35 stamps. The Village Deep is increasing its plant, and the Robinson is adding to its reduction plant stamps to crush 12,000 tons of Main Reef per month.

The only company that retired during the year 1908 is the Bonanza, a small property which had a life of exceptional prosperity. The mill was bought by the Robinson Central Deep mine and the stamps are now crushing ore from that

property. There are two other mines nearing exhaustion, namely the Champ d'Or and the Jubilee. It may be remarked that when mines are worked out, the mills are still available to crush ore from other mines, so that the productive power of the field as a whole does not necessarily suffer from the exhaustion of a mine.

EASTERN RAND DEVELOPMENTS

The most noticeable development of new ground that took place during the year was in the eastern section of the Rand. The successful results obtained by the New Kleinfontein, the Van Ryn, and the New Modderfontein mines, which are the most eastern producing mines, led to increased activity in this neighborhood, and the Main Reef series may now be regarded as proved without doubt as a payable ore deposit as far as Geduld. The extension of the reef farther east or south is still something of a problem; but that it will be traced farther in the near future seems certain. The Witwatersrand beds are in this district covered by a younger formation, so that the exact position of

the Reefs and of the lay of the beds has to be determined by bore holes.

The theory of the extension of the Rand formation most generally accepted is that the Main Reef takes a turn to the south, running toward the Nigel district. While there is some uncertainty as to its course after leaving Geduld, all doubt as to its position and value as far as that farm has now been cleared up. The Geduld mine is now one of the crushing mines, and active development is proceeding on the Van Dyk, the Brakpan, the Rand collieries, and the Apex.

Below Modderfontein, a new company called the Modderfontein B. Gold Mines, Ltd., was recently formed to amalgamate into one block of 1467 claims, of which 67 are north of the outcrop, the claims of the Modderfontein Extension, Ltd., North Eastern Claims, Ltd., Transvaal Land and Mines Proprietary Syndicate, Ltd., and South Eastern Claims, Ltd. This com-

*Consulting mining engineer. London

pany is expected to have the reef in no place at a greater depth than 2000 ft. vertical, and the active development of the property will shortly be commenced.

On Daggafontein, another farm in this district, boring operations located the reef and a shaft is projected; and on Cloverfield the sinking of a shaft is also being taken in hand. As an example of the value of the ore met with in this district, recent development returns of the Brakpan and Van Dyk mines may be recorded. At Brakpan, No. 1 shaft is 3098 ft. deep, and three levels have been driven. In No. 1 the reef is displaced by a dike. In No. 2 level a drive of 131 ft. showed over 101 ft. low grade, and over the last 30 ft. 17.44 dwt. over 29.5 in. In No. 3 drive the ore was low grade. In No. 2 shaft the reef was cut at 3695 ft., where it averaged 16.38 dwt. over 81.75 in. In a raise put up 25 ft., the reef which was only partially exposed assayed 18.36 dwt. over 64.8 in. A dike is here met with, and on the other side assays averaged 8.5 dwt. over 52.7 inches.

On the Van Dyk the total lineal development to September 30 was 8954 ft., of which 6114 ft. were on the reef, assaying over this distance 8.47 dwt. over 30 inches.

Although none of the developing mines in the far Eastern Rand has been opened yet on a large scale, sufficient work has been done to demonstrate that good ore occurs and that the district will in the future yield a large gold production. Except for the break caused by the Witpoortje fault there is now a practically unbroken line of mines from Randfontein to Geduld, a distance measured along the line of outcrop of about 50 miles. There are a few gaps here and there in this line where there are no producing mines. Between Randfontein and the West Rand Central there is a stretch not yet developed, and in the West Rand a small length of outcrop belonging to the Roodepoort Gold Mining Company is standing idle. But this will shortly again be worked, an amalgamation with the Roodepoort United Main Reef having been announced in December. In the Eastern Rand there is an unworked piece between what was the Cason (now part of the East Rand Proprietary Company) and the New Kleinfontein. With these exceptions, the Main Reef beds have been exposed and developed over the whole distance from Randfontein to Geduld.

LABOR

The decision of the Transvaal government to terminate the employment of Chinese at the mines was referred to in last year's review. At the close of 1907 there were 37,118 Chinese employed, which number was reduced to 12,317 at the end of October. Fortunately the industrial position was not seriously affected by this large reduction of labor, owing to the

increased supply of Kafirs. It is partly due to more successful recruiting and partly to a decreased demand for this labor in other parts of South Africa, notably at the diamond mines, that the Rand has not experienced a labor famine as might have been expected. On the contrary, for the greater part of the year the demand for unskilled labor has been easily met.

It is satisfactory to be able to report that the efficiency of the native has undergone improvement, largely brought about, it is claimed, by the good example set by the Chinese. The standard of work, too, has been raised, at all events, at some of the mines. At the Simmer & Jack, for example, a 48-in. hole is now expected from hammerboys in place of a 36-in. hole, and, in the case of machine drilling, an 8-ft. hole instead of a 6-ft. hole. Greater efficiency in unskilled labor was also obtained by extending the period of engagement of natives to 12 months instead of shorter periods which had previously been customary.

While there is no great difficulty at the present time in obtaining a sufficient supply of unskilled labor, anxiety has been expressed that in consequence of the great expansion in the mining industry that is now taking place, the labor question may again become a serious problem. At a meeting of the Knights Deep mine, held in November, the chairman, a manager of one of the larger financial houses, said that the labor question was only temporarily solved, but expressed the hope that an adequate supply of native labor would be obtained from Central Africa and from Zululand and the neighboring territories, from which districts so far only a small number of natives had been drawn. There is also reason to hope that a further economy of labor may be obtained by substituting machine drilling for hand drilling, a change which is dependent on the discovery of a thoroughly reliable machine drill.

Economy in native labor is also obtained by employing unskilled whites and white apprentices on an increased scale. In some of the mills, for instance, natives are excluded, their places being filled by young white men. The extent to which unskilled white labor can be employed is regulated by considerations of cost. The low rate of native wages prevents the white man from competing successfully with the Kafir for the lowest class of manual labor; but for works where intelligence counts, it is different. Here, owing to increased efficiency, he can enter into successful competition with the Kafir, and it is satisfactory to find that those who control the mines are encouraging this competition, and are giving facilities to young men of the country to make themselves efficient miners, enabling them to find employment in positions which were formerly occupied by natives.

The total labor employed in all mines of the Transvaal, that is, including gold, coal, diamond and base metal mines, during September, was: Whites, 20,732; colored labor, 176,129; Chinese, 16,311.

AMALGAMATION OF COMPANIES

During the year 1908 a number of amalgamations of companies were carried through. From one end of the Rand to the other the policy of creating larger units than formerly has been adopted. Whereas the standard size for a mining block used to be 200 claims, the area now selected as a unit is 1000 claims and more. In support of the adoption of this policy, it is urged that larger units produce economy in capital expenditure and a reduction in working costs, principles which will not be contested. The differences of opinion that have arisen have not been so much on the question of the size of a mine area, but on the valuation placed on the different interests included in the amalgamation, and generally on the question whether increased area and increased life, even though accompanied by a reduced cost of working, were worth the price. Many shareholders in a producing mine sufficiently developed to allow of there being no uncertainty as to its future, prefer their property to be worked out to a finish, rather than have a speculative piece of additional ground added at a considerable increase to their capital and consequent reduction in their dividend.

Although economy in working has been the main reason put forward in support of consolidation and amalgamation, the policy has also been largely influenced by financial considerations. In some cases the deep level areas, which have been amalgamated with producing mines immediately above them, have belonged to companies which had either exhausted their working capital, or had not sufficient funds to bring them to the producing stage. The mining houses who controlled them expressed their inability to obtain the necessary capital from the shareholders, or the public, and were not prepared to finance these companies from their own funds. The Simmer Deep, the City Deep, the Knights Central, the Jupiter, and the East Rand amalgamations may be quoted as

examples of consolidation brought about largely for financial reasons. A later example is the proposed amalgamation of the South Nourse with the Nourse Mines, the latter a company which had been not long ago joined to the outcrop mine, the Henry Nourse, an amalgamation which was attended with unfortunate results for the outcrop mine.

The position at the commencement of 1908 was that many deep-level companies were in a desperate financial condition. Their funds were exhausted, or insufficient to bring them to the producing stage. Fresh capital was wanted and was not obtainable, and it was evident that even if fresh capital was obtained it would be a long time before these properties would be able to pay dividends. The adoption of the policy of amalgamation saved the situation. By consolidation with the producing mines the necessity of raising fresh capital was avoided. The shareholders in the deep mines became partners in the dividends of the producing mines, giving in return their ground and whatever cash assets they happened to possess. The producing mines received as compensation for the increase to their capital the prospect of an extended life and were enabled with the funds supplied by the deep mines to work on a larger scale and consequently at a reduced cost of working.

The arguments used in favor of amalgamation mostly employed have been the arguments of longer life and of reduced working expenses which the working of larger areas brings about. There can be no question that the working of larger units tends to economy. There will be obviously a saving in administration expenses, while economy will be gained in having larger power plants. Fewer shafts are required, and the development of a mine can be carried out more advantageously with a large than with a small area.

The statistics of the working costs of the mines, which will be referred to presently, demonstrate the advantage of large units.

In principle, therefore, amalgamation into large units is sound. The question whether amalgamation or consolidation is advantageous or not depends on what valuation is put upon the various interests. And it is on this point that differences of opinion as to the justice of the amalgamations that have been carried through have arisen. Valuations are governed by many factors, some of which are arbitrary, such as the scale of operations, capital expenditure, rates of interest assumed in calculating the present value of profits, so that it is not surprising that conflict of opinion should arise as to the fairness of any scheme of amalgamation.

The question is, what is the most economical life of a mine, and the relation between capital expenditure and profits has been the subject of much discussion, and prominent engineers, such as Mr. Kötze

and Ross Brown have shown that the economic life of a given area comes inside 10 years. If that is so, the argument of long life, which deep-level interests put so much weight upon, has to be treated with caution by the producing mines. They have to decide whether the present value of the profit to be secured from the deep ground is worth the price demanded, taking into consideration the decreased cost of working that the amalgamation will bring about owing to the increased scale of operations, a result which, it may be noticed, can be secured without amalgamation by devoting some of the profits to extension of plant.

From what has been said, it will be understood that amalgamation schemes require very careful valuation work, and it is only fair to say that the Rand mining houses have, in all the most important consolidations at all events that have been carried through, employed competent engineers to value the various interests involved.

The undesirable feature in these amalgamations is that the sellers are those who practically decide the price. Valuations are made by engineers, it is true, but if the valuation does not agree with the views of the financial house, the business may be dropped. In several cases the complaint has been made that the shareholders in the producing and dividend-paying mines have been forced to become partners in ground of unproved and speculative value without any real necessity. Unamalgamated, such mines had prospects of a certain, though limited prosperous career. The Henry Nourse, the Village Deep, and the East Rand producing companies could all have been worked to a finish without amalgamation. The shareholders in these mines hear of the advantages to be gained by amalgamation, but not the disadvantages, and probably if more prominence had been given to the disadvantages, the shareholders in the dividend-paying mines would have refused acceptance of the respective schemes of amalgamation. Opposers of a scheme have not, however, the same chance of making themselves heard as the promoters, and consequently the financial house, although perhaps representing a minority interest in the producing mine, generally wins the day.

RAND FINANCE

This may be a convenient place in which to notice the methods employed to restart some of the mines whose working capital has been exhausted. The usual practice is now for the capital to be first reduced by giving the old shareholders one share for each two, three or four held before. The capital is then immediately raised and the fresh capital is offered *pro rata* to the shareholders with options over further shares at varying prices and payable at varying dates, the controlling

house taking options over some of the shares. Examples of this form of reconstruction are the Bantjes and Vogelstruis Consolidated Deep.

It seems a pity that the finance of mining companies cannot be conducted on simpler lines and that the complicated system of reducing capital and then immediately raising it, coupled with all sorts of option conditions, cannot be avoided. These complicated methods of finance, approaching almost to juggling, are exceedingly puzzling and unpopular with the ordinary shareholder.

Another matter connected with Rand finance that seems worth calling attention

to, as it is something of an innovation, is the building up of a reserve fund out of profits and its investment in a new undertaking. The Jumpers mine is an example of this. This mine is nearing exhaustion, but the profits are not being fully distributed to the shareholders, but reinvested in another mine in the East Rand, the Chimes West and Benoni. It seems to me that shareholders would much prefer to make their own choice in selecting an investment for their profits. This practice of investing profits in outside properties, as well as the practice now largely prevalent of increasing the reduction plants out of profits instead of by an issue of new capital, is evidence that the Rand mining houses, having failed to get money from the public for new enterprises or for extensions, have adopted a policy of making the shareholders in the dividend-paying mines find the money.

MINING INDUSTRY COMMISSION

The report of this commission was issued in March. The commission had been appointed by the government to inquire in what direction, and how far, the use of mechanical appliances could be extended on the mines, and what effect such extended use would have upon (a) the employment of white labor, (b) the cost of production (c) the demands of the mining industry for native labor and (d) on the mining industry generally. The commissioners were also asked to report on the means best calculated (a) to increase the employment of white labor on the mines, (b) to secure the more efficient use of native labor and (c) generally to secure greater economy and efficiency in mining operations.

The commissioners were not unanimous in their findings and there was a majority report representing the views of F. H. P. Creswell, a prominent advocate of all-white labor for the mines, and a minority report, which expressed the views of the average mining man on the Rand, which are that the present condition of things do not call for any drastic changes by legislation. The government appears to share this opinion. At all events no action has been taken to carry out the principal recommendations of the majority report.

OTHER MINERALS

The following statistics of the Mines Department give the production of other minerals in the Transvaal for the statistical year 1907-1908:

	Value.
Copper ore.....	£32,400
Galena.....	21,761
Tin ore.....	81,677
Magnesite.....	900
Flint.....	12,350
Lime.....	52,474
Miscellaneous.....	17,364
	£218,926

STOPE-DRILL COMPETITION

During the latter end of 1907 a competition for machine-stope drills, promoted by the *South African Mining Journal*, was held, and excited much interest. Eight different makes of drill entered, the prize being awarded to the Gordon drill. The advantages to be gained from such trails are recognized by the mines, and a further competition on a larger scale is being organized by the Chamber of Mines to take place about April, 1909. The competition is expected to last more than six months, so that a thorough testing of the compet-

ment, but its application is limited to government land and private farms not beneficially occupied.

DIVIDENDS

The dividends paid for the first half of the year amounted to £4,085,694, of which amount £3,975,071 was paid by 42 companies in the Witwatersrand district and £110,623 by three companies in the outside districts. The second half-year will show a considerable increase; and the total dividends for the year may be expected to be about £8,500,000.

ing drills may be made. Entries for this competition closed on Dec. 31, 1908.

The object of the competition is to obtain a small drill, weighing less than 100 lb., that can be used in narrow stopes. The first prize of £4000 will be awarded to that drill for which the total cost, when divided by the total footage drilled by all machines of that entry during the competition, is least. There will be a second prize of £1000, besides special prizes for the drillmen. Having regard to the great saving in native labor that the discovery of a suitable drill would bring about, the competition promises to be of great importance to the industry.

METALLURGICAL AND MECHANICAL IMPROVEMENTS

In metallurgical work several improvements appeared during the year. The new stamp batteries are being equipped with heavier stamps than formerly, the latest mills having stamps weighing 1650 and 1700 lb. Appliances are being put in for dewatering sands. A 15-ft. rotary sand filter, after the designs of W. A. Caldicott, is now running at the Simmer & Jack, and others are to go up at the new Simmer Deep plant. Attention is being paid to the removal from the tailings pulp by a magnetic separator of metallic iron, which otherwise accumulates in the tube

NEW GOLD LAW

A draft of a new gold law was published early in the year and met with considerable adverse criticism. The law was then referred to a select committee with the result that a gold law has been agreed to and is expected to come into force on Jan. 1, 1909. Although not entirely satisfactory from the point of view of the mining community, it has been accepted as an improvement on the old law. It is more liberal than the former law as regards prospecting. The principle of open prospecting has been agreed to by the govern-

ment. At the Robinson Deep a magnetic conveyor belt pulley is going in to pick out broken drill ends, etc., so as to keep them out of the mortar boxes. At the Rantjes mill the plates are to be placed in a separate building, while an outside stockpile and belt system will allow of reduced bin construction.

Warm solutions for slime treatment are doing well, and the system will probably be extended. At the Simmer Deep plant a large vacuum air pump, drawing 420 cu.ft. per min. has been installed and connected up to the sand-leaching pipes, so as

to drain charges thoroughly and draw large volumes of air through the sand.

Electric stamp driving is carried on at some mills, some of the mines obtaining their power from their own central station while others purchase from an independent supply company. H. C. Behr's dense-air system is at work at the Simmer Deep

Ontario

By THOS. W. GIBSON*

Silver and nickel dominated the mining industry in the province of Ontario in 1908. There have been two eras of silver production; one began with the discovery

value, but the deposits were not so rich as those of Cobalt, and the latter camp has doubtless already surpassed the Lake Superior field in production.

The second era began with the discovery of Cobalt five years ago, since which time a total output of approximately 35 million ounces of silver worth say 19½ millions

mine. The exhaust of a winding engine are being put in to do the work of the large tailings elevator wheels which are so conspicuous all over the reef. Particulars were given in the JOURNAL of Sept. 12, 1908.

At some of the mines centrifugal pumps are being put in to do the work of the large tailings elevator wheels which are so conspicuous all over the reef. Particulars were given in the JOURNAL of Sept. 12, 1908.

of Silver Islet in Lake Superior 40 years ago and was prolonged by the subsequent opening up of the Rabbit Mountain, Badger, Beaver, Silver Mountain and other mines on the mainland. Production came to an end, however, when silver fell from its high estate. Statistics for that period are now unobtainable, so no definite statement can be made either in ounces or

of dollars has been made. The development of the Cobalt camp is strikingly shown by the following table:

PRODUCTION OF SILVER FROM COBALT.		
Year.	Production, Oz.	Value.
1904	206,875	\$ 111,887
1905	2,451,356	1,360,503
1906	5,401,766	3,667,551
1907	10,023,311	6,155,391
1908.	17,000,000	8,200,000
Total.	35,083,308	\$19,495,332

The figures for 1908 are based on the

*Deputy Minister of Mines, Toronto, Ont.

output for the first nine months of the year, and are not likely to be far out of the way. For this period the production was 12,581,510 oz. The shipments for the same time amounted to 17,335 tons; consequently the average silver content of the ores shipped was 725 oz. per ton. This is an improvement over 1907, when the average had fallen to 677 oz. as compared with 1013 oz. in 1906. The improvement is, in part, due to the great richness of some of the veins opened during the year, and in part to the fact that the shipments this year included about 480 tons of concentrates, the product of the mills which several of the companies have erected to treat their low-grade ores.

The sensation of the camp in 1908 was furnished by the Crown Reserve mine. A portion of the bed of Kerr lake, containing about 23 acres, had not been staked out as a mining claim notwithstanding it was in juxtaposition to such mines as the Drummond, Kerr Lake, Lawson and Foster. In 1906 the Ontario government offered the parcel for sale to the highest bidder. The best offer received was \$52,000, which was not considered high enough. Offers were invited a second time with the condition added that the purchaser should pay 10 per cent. royalty on the value of the output at the mine. The bids this time went up to \$178,500. The buyers (a syndicate of Montreal brokers) formed a company, and for a time the shares sold for 15 to 20c. A diamond drill located a vein which for size and richness in native silver is probably not surpassed in the camp. Shares are now worth about \$2.70, and the government's decision to reserve a royalty will undoubtedly put a large sum in the treasury of the Province.

THE PRODUCING MINES

The leading mines of 1907 continued their production in 1908, and most of them increased their output. Among those were Nipissing, La Rose, Coniagas, O'Brien, Kerr Lake, Trethewey, Silver Queen, Temiskaming, Temiskaming & Hudson Bay, Townsite, Right-of-Way and others. Crown Reserve was the chief producer added during the year. Temiskaming came well to the front, and is of interest from the fact that its leading vein is in the Keewatin formation, which at Cobalt is less prolific in silver-bearing ore than the conglomerate.

Most of the ore is still shipped out of the camp for treatment, the low-grade or "screenings" going principally to Denver, Colo., where it has been found suitable for mixing with ores from certain of the Western mines. Low-grade ore in Cobalt contains 100 to 150 oz. per ton. The high-grade ore which carries up to 7000 and 8000 oz. per ton is treated principally at the Canadian Copper Company's smelter at Copper Cliff, and the Deloro Mining and Reduction Company's works at

Deloro, both of these plants being in Ontario. The latter is owned chiefly by the proprietors of the O'Brien mine. The Coniagas smelter at Thorald on the Welland canal, went into commission during the year, and operated on the product of the Coniagas mine.

There were no labor troubles at Cobalt in 1908, but the declining value of silver undoubtedly had a tendency to lessen production. The cost of producing silver is put by some of the leading Cobalt mines at 9 to 10c. per oz., so that even at 48 or 49c. there is a good margin of profit.

That the mines of Cobalt yielded nearly 60 per cent. more silver than those of any one State in the United States even at low silver prices is proof of the remarkable character of the deposits.

OUTLYING DISTRICTS

Extensions of the Cobalt silver field continue to be eagerly sought for and several have been found. The chief of those are: (1) South Lorrain; (2) Montreal river; (3) Everett and Miller lakes; (4) Gowganda lake.

South Lorrain is a patch of unsurveyed territory on the west shore of lake Temiskaming, and south of the township of South Lorrain proper. The formations are similar to those in the vicinity of Cobalt. Most of the promising veins have been found in the Keewatin but good silver ore has also been obtained from veins in the diabase. The chief properties in South Lorrain are the Keeley (H.R. 19), and the Haileybury Silver Mining Company.

The Montreal river runs in a southeast course for many miles before falling into lake Temiskaming, and about 40 miles northwest of Cobalt, in James township and vicinity, some good finds of silver have been made. The geology is similar to that of Cobalt except that the diabase is more prevalent, and in this the silver-bearing veins chiefly occur. Numerous claims have been staked in James, Smyth and Tudhope townships and also in Hubert, Silver, Bloom and other lakes. The Otisse, Downey, Gifford, Currie and other claims in the district and the Darby and White groups at Maple Mountain have promising showings. The last-named has been acquired by the Canadian Ores, Ltd., an English concern.

Miller and Everett lakes lie farther west in the Temagami forest reserve, and a number of excellent discoveries were made here and also at Gowganda lake, still farther west, whence some very fine samples of native silver have been brought during the year, resembling the bonanza finds made at Cobalt in 1903 and 1904. Gowganda claims most attention at the close of the year as the new silver field, "Snowshoe" staking is actively going on at present, and the coming of spring will undoubtedly see a big rush. Careful ob-

servers, comparing conditions with those at Cobalt, doubt whether the veins in any of these fields will prove so rich or permanent.

MANUFACTURE OF COBALT OXIDE

The cobalt-oxide industry suffered from the excessive supply of cobalt ore thrown on the market as a by-product from silver smelting. The world's consumption of oxide annually falls far short of the production from the mines of Cobalt, and consequently the price of oxide fell from \$2.50 to \$1.40 per lb. The only relief is on a widely extended use for cobalt, which is, at present, chiefly employed in making the color known as cobalt-blue.

NICKEL AND COPPER

The output of the nickel-copper mines of the Sudbury district for 1908 was probably slightly less than in 1907. The general slackening off in the iron and steel trades has lessened the demand for nickel, and during the last quarter of 1908 mining and smelting operations were considerably curtailed. The nickel production of 1907 was 10,972 tons; for the first nine months of 1908 it was 7760 tons. Allowing for the falling off toward the close of the year, the output for 1908 was probably not more than 10,000 tons. The copper production will be about the same as in 1907, say 7000 tons. The leading producers continued to be the Canadian Copper Company and the Mond Nickel Company. The former's works at Copper Cliff were completed and well equipped. Ore was raised mainly from the Creighton mine, which is high in nickel and from the Crean Hill, which is rich in copper. The Mond Company's plant is at Victoria Mines, and its orebodies are at the latter place and in the township of Garson. A new concern, the Dominion Nickel Copper Company, has begun work on the northern range, where it controls a number of important deposits some of which, notably the Whistle, rival in size any yet opened on the southern range. The construction of the Moose Mountain branch of the Canadian Northern railway has provided the necessary shipping facilities, and the company proposes to develop water power on the Wahnapitae river for use in its mines. The parties principally interested are Canadian capitalists.

IRON ORE

Iron ore was produced from the Helen mine at Michipicoten and several deposits of magnetite in northwestern and eastern Ontario, the total tonnage raised being probably about the same as that of 1907, which was 205,295 tons. Search for workable bodies of ore in the extensive ranges of northern Ontario met with some reward. Moose Mountain beyond doubt contains a large quantity of good ore, and at Emerald lake, Steep Rock lake.

Woman river and elsewhere, diamond drill and other work was done on promising prospects. The pig-iron product of 1908 will probably be rather less than that of 1907, owing to the stoppage of the Deseronto and Port Arthur blast furnaces.

OTHER MINERALS

In certain nonmetallic substances, older Ontario is rich. These include petroleum, natural gas, salt, mica, corundum, talc, graphite, feldspar, etc. The first three are obtained from the limestones of Devonian and Silurian age which underlie the southwestern peninsula or that part of the province north of Lake Erie and east of Lakes St. Clair and Huron. The oilfields of Petroler and Oil Springs continue to produce through thousands of wells the average yield of which is not more than one-quarter barrel per day; but the new field of Tilbury East now contributes at least 50 per cent. of the yearly output. In 1907 the total production was 27,621,851 Imp. gal. and in 1908 it was probably about the same, the greater flow of the new territory compensating for the declining yield of the older fields.

During recent years natural gas from the counties on the north shore of Lake Erie has been produced in increasing volume, and is now supplied to a number of cities and towns within reach of distribution. Chatham, St. Catharines, Hamilton, Brantford, Niagara Falls and other places are enjoying this cheap and convenient fuel, and preparations are being made to pipe gas from Kent county to Windsor and Walkerville. Gas still goes in considerable quantity from the wells in Welland to Buffalo, but the domestic consumption is increasing much more rapidly than the export. In 1907 the value of the natural gas produced in Ontario was \$756,174, and in 1908 the output, in all probability was greater.

The salt production of Ontario is about \$400,000 annually. The seat of the industry is the east shores of Lakes St. Clair and Huron, and the practice is to pump up the salt as brine and evaporate it.

Iron pyrites is abundant in eastern and northern Ontario, and the quantity raised has risen from 7469 tons in 1903 to about 19,000 tons in 1908. A good deal is exported to the United States, but a considerable part of the output is used in the manufacture of sulphuric acid at Sulphide in Hastings county.

The production of construction materials, of which Ontario contains a profusion, goes on steadily. Bricks, lime, stone and portland cement are produced in older Ontario within easy reach of market. Of portland cement the output increased from 2,033 bbl. in 1891 to 1,853,692 bbl. in 1907, and probably a larger quantity in 1908.

In all, the value of the mineral produc-

tion of Ontario during 1908 will be, say, \$28,000,000 valuing the products at their selling price at point of production.

Klondike District

By JOHN POWER HUTCHINS*

The gold production for the Klondike district in 1908 was about \$3,300,000. This is slightly more than that of 1907. The following tabulation shows the gold production for Yukon territory, which includes Klondike and several other districts, since the discovery of gold in the Klondike. Most of the gold produced by Yukon territory has come from the Klondike.

GOLD PRODUCTION OF YUKON TERRITORY.

1896.	\$300,000
1897	2,600,000
1898	10,000,000
1899	16,000,000
1900	22,275,000
1901.	18,000,000
1902.	14,500,000
1903.	12,250,000
1904.	10,350,000
1905	7,000,000
1906	6,000,000
1907	3,150,000
1908 (estimated)	3,500,000

These figures show a rapid increase to a maximum output and then a gradual decrease representing a history similar to that of other placer districts. For the past three years the Klondike has been in a transition period. The one-man enterprise has had its day, and now a powerful corporation has control of several of the richest creeks. During these three years preparations have been going on to work these creeks on a large scale with dredges and other machines and a system to supply water for hydraulicking has been in the course of construction. It is expected that this will be finished early in 1909. When operations on a large scale are under way, an increase in the gold output may be expected.

DREDGING GROUND

The discovery of rich and extensive gravel deposits in the Klondike district in the future is improbable. There is no such intricate and large system of "dead rivers" as in California and the total volume of gravel in the Klondike that may be worked profitably is considerably less than the profitable dredging ground remaining in California, but which can not be mined because of anti-debris legislation. The principal deposits that will be worked are the creek beds and the "white channel."

The "white channel" is what is left of the ancient creek beds; it has a course approximately parallel to the present creeks but at an elevation from about 100 to 300 ft. above them. Where it has not been eroded, this channel usually appears

with one rim completely removed. Locally, it is called a "bench deposit." There is one notable exception in the occurrence of the "white channel;" this is the deposit between Lovett Gulch and the Klondike river where the two rims are intact for several thousand feet.

NEW METHODS

There was little novelty in the mining methods introduced in 1908. Dredging was carried on with better results than in 1907. This was due to several causes. Steam thawing was employed on a larger and better scale, and there were fewer attempts to dredge frozen gravel. Stripping had been found insufficient to thaw gravel to bedrock unless carried to such a depth as to leave a shallow gravel section. It had been found that thawing progressed to but a slight depth into gravel below the water level. Draining the gravel with cuts will be applied.

It is expected that stripping and draining with cuts 20 to 50 ft. apart will result in progressive thawing to bedrock, after the thawing of one or more summer seasons, and that this thawed ground will remain unfrozen. It is yet to be determined whether ground thawed during the summer, no matter by what method, will not freeze again during the subsequent winter and so make it necessary to thaw it again every summer. It is certain that gravel which has been stripped, drained and thawed has frozen again on hillsides where there was a southern exposure and where thawing had progressed to a depth of above 25 ft. in one summer. It may also be observed that in many creek beds both in Yukon territory and Alaska, frozen ground is often found even where there is no muck overburden. Frozen ground is also found where gravel is dry and has no overburden of any sort.

The average temperature for the year is considerably below the freezing point. The minimum temperatures are also considerably more below than the maximum temperatures are above freezing. Whether ground thawed in the three to four months of summer will remain thawed during the eight to nine months of winter, unless in some way protected from the extreme cold, is a matter of doubt. It is possible that flooding the thawed ground will protect it from the cold of the air. There would be a penetration of superficial frost to a depth of several feet even if the ground were so flooded. Whether the fact that the heat of thawed ground is reduced by the cold of adjacent frozen ground will have any important bearing, is an important consideration.

Frozen ground has been observed to a depth of more than 220 ft. in the Klondike. This means that between this depth and the surface, the ground temperature is less than 32 deg. F.; otherwise frost would not penetrate to such depths. As

*Mining engineer, 52 Broadway, New York.

far as known, no accurate or detailed data as to ground temperatures have ever been taken in the far North. It is entirely probable that investigation will show ground temperatures considerably less than 32 deg. F. Where the average temperature of the air is about 20 deg. F. below the freezing point, it is not inconceivable that the ground may have, after exposure through geologic time, acquired a temperature below 32 deg. F.

It is to be hoped that thawing can be done as anticipated, for the same methods could be applied elsewhere with the opening of much ground, now thought undredgable because of its frozen condition, for lucrative exploitation. A considerable gold content insures success if thawing can be done cheaply.

ELECTRIC ELEVATORS

The operation of the new elevators installed during the year is as follows: Material of the creek bed is driven by hydraulicking with gravity water to a point at the base of a bucket elevator. This elevator lifts most of the material and some of the water to the sluice, the rest of the water being lifted by centrifugal pumps. The elevator and pumps are driven by electric power.

The greatest difference between this machine and those tried some years ago is in the buckets. The new buckets are more powerful and heavier and can, if necessary, excavate material that may have compacted after driving to the sump. The buckets are larger and can therefore handle larger boulders than could any of the older machines.

These elevators were installed in narrow creek beds and on bedrock for which floating dredges are not supposed to be well adapted.

The elevators must be moved occasionally, and it has not yet been determined how often this will be necessary or how large an acreage can be worked at one setting. They can not be called mobile as compared with other placer-mining machines, especially with floating dredges. There is also the difficulty of tailings disposal which is a direct result of immobility. Placer-mining machines should be easily movable for two important reasons; they must keep up with the excavation and out of the way of the tailings.

This type of machine is said to have worked well during part of 1908. The year was normal in most respects. There had been a heavy snowfall and this melted slowly, allowing considerable ground sluicing of overburden from the creek beds. The rainfall in the aggregate for the summer was about $5\frac{1}{2}$ in. The time of the freezeup was normal.

LABOR AND THE MERGER

Since the merger of claims on Bonanza, Eldorado and Hunker creeks there has

been practically no winter drifting, and there has been less of this kind of mining on most of the other creeks. There were a few dumps taken out on Quartz creek where "lays" were about 65 to 70 per cent. of the output to the "layman."

The labor supply was augmented by men brought in from Vancouver, and it was ample until autumn, when the demand was greater than the supply. There were no labor troubles, although difficulty was threatened when it was thought that large numbers of cheap laborers would be brought to work for the merged interests. Wages are still high; about 40c. per hour with board is the general pay for unskilled labor.

No paying quartz mines have been developed in the district. For several years work was done on a vein on Bonanza creek, but this has been stopped. At present considerable interest is being taken in some quartz prospects on the Dome, a mountain dominating the topography near Dawson and from the flanks of which several of the richest Klondike creeks radiate.

HYDRAULIC MINING

Hydraulic mining was carried on as usual; about three times as much material, or about 3,500,000 cu.yd., was washed as in 1907. The cost of hydraulicking did not vary much. It is probable that when water from the new ditch is available, a considerable reduction will be made. A duty of 8 cu.yd. per miner's inch per 24 hours was attained some years ago where about 275 miner's inches was used. Several factors influenced this result, the most important being an 8-per cent. grade, good dump and gravel of a favorable admixture of fine material and having no large boulders. A bedrock favorable for running and maintaining cuts assisted in keeping them close to the banks at all times so that little time was lost in "driving." There will be an opportunity of making some new records in the duty of the miner's inch, when a large volume of water is applied on the White channel.

The Klondike climate, with its extreme cold and the frozen ground, is hard on earth work. It is difficult to maintain roads, dams and ditches. Thawing results in the sloughing off of material from the banks of ditches, and where the course of the ditch is over "muck" and on northern exposures the strictest vigilance is needed to prevent serious breaks.

COSTS

The cost of dredging is said to have varied from about 15c. per cu.yd. for a 7-cu.ft., close-connected bucket dredge in unfrozen ground to about 20 to 35c. for similar dredges working in ground originally frozen in part and thawed by stripping and steam thawing. An anti-

quated dredge of small capacity operating in partly frozen ground showed a cost of about 60c. per cu.yd. Thawing for dredging costs from 10 to 20c. per cu.yd. No figures are yet available for dredging solidly frozen ground, and the cost of thawing such material is not yet known. All the dredging done up to the present time has not been in what is locally called badly frozen ground.

Wood hauled in 16-ft. lengths on wheels cost about \$14 per cord. Supplied in large quantities it was sold for about \$8 per cord, where it could be rafted and floated down the Klondike river without much hauling.

Less coal was burned in 1908 than in previous years. The coal available has been found to possess poor steam-producing qualities; it makes dirty fires and much ash and clinker. One ton of coal has been found to have about the same calorific value as one cord of wood, and since wood can usually be purchased for less than coal it is generally used.

Dredging in Russia

There were 64 dredges at work in the Urals and the Yenisseisk district in 1908, according to the *Torg. Prom. Gazeta*. Of these 25 were in the Urals and 39 in the Yenisseisk jungle, Siberia. Fairly detailed reports have been received on the working of 46 of the dredges, which produced on an average 2 poods 6 funts and 67 solotniks. Their total working hours were 99,406, and they washed 594,405 cubic sajens of sand. The total production of gold and platinum was 99 poods, 28 funts, 21 solotniks, 17 doli (52,467 oz. Troy). Compared with the preceding year, the amount of ground worked per hour has increased by nearly 15 per cent.

The California and Gulf (excluding the Corsicana) crude oils are, according to *Petroleum Review*, Aug. 15, 1908, the heaviest in the United States, but in both fields there are considerable variations in the specific gravity, especially in the California fields where considerable crude oil as heavy as 12 deg. B. and considerable as light as 30 deg. B. is found.

In 1908 two electric steel-making plants, according to the *Electrochem. and Met. Ind.*, January, 1909, were in operation in the United States. These use Héroult furnaces. In Europe there are 22 Héroult furnaces already in operation or being built: 11 Stassano furnaces; 8 Girod furnaces; 10 Kjellin furnaces, and 10 Roehling-Rodenhauser modified induction furnaces. In the United States a few small Colby induction furnaces are in operation, mainly for experimental work or for demonstrations.

Production of Other Metals and Minerals

Aluminum — Barytes — Borax — Phosphate Rock — Quicksilver —
Cyanamide — Statistics of Production — Commercial Conditions

The most important development in the aluminum industry was the cut in the price of that metal, in October, from 33c. to 22@24c. The phosphate output of Tennessee showed a marked decline in 1908. There were important changes in control of properties and several new companies were organized. The barytes industry suffered greatly through lack of demand and foreign competition.

Although the production of quicksilver was practically the same as in 1907, the average price for the year was considerably higher, notwithstanding the fact that the production in California, the chief source of the metal, exceeded the demand. The borax industry was characterized by a year of continued low prices, which caused the closing down of many of the mines in California, the only State in which the mineral is produced. With the building of the plant of the American Cyanamide Company at Niagara Falls, a new industry is introduced in North America.

Barytes in Tennessee

By A. H. FAY*

Little work was done in the barytes industry in Tennessee during 1908. The majority of the mines were closed down the latter part of 1907, and only a few of the very best properties were operated the following season. The price of the ground and floated product was low, and the demand so limited that it has been difficult to place this material on the market at a profit.

While labor is cheap in the South, the actual cost of mining is high, for the reason that the deposits are pockety, uncertain and very irregular in size, which prohibits the installation of steam shovels and a good tramway system. The majority of the workable deposits are at a distance from the railroad, necessitating an average haul of five miles by wagon over very poor roads. This freighting is usually done by the farmers living in the immediate vicinity of the mine at the rate of \$1.25 per long ton for a five-mile haul.

The mining as carried on in this section (Sweetwater) is all open-pit work, with pick, shovel and wheelbarrow. The barite occurs as nodules in a tough residual clay, and it is necessary to use some powder to break the heavy clay. The mining cost varies from 75c. to \$2 per long ton, depending largely on the amount of

ore in the clay, and the depth of the overburden. The royalty is usually 25c. per ton.

A very large percentage of the ore mined from these clay deposits has a scale of limonite inclosing the barite, which on account of the small difference in specific gravity of the two minerals, is very hard to separate by the present milling method, i.e., jigging. Unless a good separation is made before grinding, it is a very difficult matter to bleach the barite thoroughly. There is a field here for much improvement.

SWEETWATER DISTRICT

Most of the mining last year was in the Sweetwater district, the principal operators being John T. Williams & Son, W. D. Gilman & Son and R. B. Doherty. The output, however, was very small. A portion of the raw ore was shipped to St. Louis. Gilman & Son operated their plant in a small way most of the year. In addition to their plant for bleaching barytes, they have a small plant for manufacturing about one ton of barium-carbonate per day.

A little work was done in Cocke county near Wolf creek, in what is known as the French Broad district. There are at least two good properties in this county, one owned by the Commercial Mining and Milling Company, which produces a very white, crystalline ore, occurring as a vein in quartzite. The other one is owned by John T. Williams & Son and has been opened enough to insure a large tonnage of cheap ore from a 7-ft. vein between sandstone strata.

At Bristol, Tenn., John T. Williams & Son remodeled their bleaching plant; took out the bur mills and added tube mills for fine grinding. The capacity of the plant is 30 tons of finished product per day. It was in operation only about one-quarter of the year. A plant for the manufacture of barium-chloride was built which has a capacity of 10 tons of crystals per day. The crude material used in the manufacture of the barium-chloride consisted largely of jig tailings, slimes and very irony ore. The ore is mixed with coal and given a reduction roast in an 80-ft. rotary cement roaster, yielding a mixture of barium sulphide and carbonate. This is leached with hydrochloric acid, which is also manufactured at the plant. The chloride liquor is then filtered, purified by a secret process, evaporated to saturation point and then allowed to crystallize.

The barytes industry in the United States is not large, and it is a very difficult mat-

ter to compete with the foreign manufacturers. There is undoubtedly a large amount of ore in western Tennessee, North Carolina and northern Georgia, and to make the most out of these natural resources it will be necessary to evolve a more economical and efficient milling and bleaching system.

Borax

Although California is the only State in the United States which produces the borates commercially, the prices for borax have fallen so low that most of the mines have ceased operations entirely; indeed nearly all of them have been closed down for a year or more, with little expectation of starting up again for some time. In some instances the plants have been removed altogether, and the properties closed for good; this is particularly the case in the neighborhood of Daggett, San Bernardino county, where the low-grade marsh muds, or superficial deposits, were being worked. Even the old colemanite mine at Calico, for many years the most productive mine in the State, has been permanently abandoned, as it has been virtually worked out by the Pacific Coast Borax Company. Some of the companies operating in that district produced in 1907, but none of them did during 1908. The companies which were working in Ventura county also closed down their properties in 1907, and they will remain idle indefinitely, for the long haul to market makes the cost of production too expensive in that region.

Refined borax, which now sells at about four cents a pound, brought about seven cents for a long time. Some of the companies made very little profit even at the latter figure and when so marked a reduction occurred in 1907, there was nothing for them to do but quit work.

It was about August, 1907, when the Pacific Coast Borax Company reduced the prices of the manufactured product; very shortly after that all the borax properties of the State, with the exception of the Lila C. mine belonging to the Pacific Coast Borax Company in Inyo county, ceased operations. In August, 1907, this company ceased operations entirely at Daggett and Calico in San Bernardino county, removed its plant, and commenced its activities in Inyo county. This move had been contemplated for several years, during which period the mine was being developed; so when the new railroad near the mine was com-

*Mining engineer, Brooklyn, N. Y.

pleted the company concentrated its efforts at the new property. The deposit is a very extensive one, and being well developed, is in a position to make even a much larger annual output than the demand requires. The grade of ore mined is high and the facilities excellent for working, though labor is high in that region. The company being enabled to produce largely at less cost than, formerly, was enabled to reduce prices, and thus put its competitors "out of business." Those companies which ceased producing in 1907 were the Western Borax Company, of Inyo county, the American Borax Company, the Western Mineral Company and Palm Borate Company of San Bernardino county, and the Columbus Borax Company and Frazier Borate Company, of Ventura county. None of these resumed operations in 1908 at former points of production, though some have exploited new fields.

There are many known borax deposits in the Death valley region; several of these are controlled by the Pacific Coast Borax Company, but others which with the present means of transportation would not pay, are still unlocated. The fact is that there has been an overproduction; so the larger companies are trying in every way to increase the use of borax products, and have done some experimenting in order to find new uses for boron compounds.

The only new properties of note are those of the Borax Properties, Ltd., a company backed by English capital, which in 1908 bought the property of the Palm Borate Company of Daggett, and also considerable other ground in that vicinity. The company has been engaged for some months in erecting a plant and carrying on extensive operations. The property has not produced any mineral, as only development has been done so far. However, the company expects before long to put its product on the market.

The Sterling Borax Company is the most prominent of the new concerns. It owns the Ventura County mines of the Stauffer Chemical Company, formerly known as the Frazier Borate Company, the mines of the American Borax Company at Daggett, and the new deposit found a year or so ago at Lang station in Los Angeles county. The refining plants at San Francisco, Chicago and New Brighton are all combined in this organization. The deposit is a vein of colemanite of good grade and is in a locality where the cost of production is cheap, as there is plenty of water available and the price of labor and of transportation is low.

The vein varies in width from a few inches to 10 ft. being like most of such veins, of a "pockety" nature and varying more or less in size. The owners of

this property state that they are able to compete in output and price with any other mining company of the State. The mine began to produce about three months ago. The product is shipped from Lang's station to Chicago, New Brighton and San Francisco, the ore being shipped crude as mined, and then refined at the points named. About 700 tons monthly have been produced thus far but this amount can be readily increased when desired.

The mines of the Pacific Coast Borax Company and the Sterling Borax Company are the only two properties in the State which produced much borax in 1908. These figures of output are not available, but it is not probable that the total yield for the year was much over 50,000 tons crude.

As stated, under present conditions, there is little or nothing in the borax-mining industry for any companies except those with extensive high-grade properties, near points of railroad transportation, and with the prevailing low prices there can be little profit even for properties with exceptional advantages.

Calcium Cyanamide

In Europe progress in the manufacture of calcium cyanamide has been rapid and satisfactory. There are 11 plants in process of construction, or in operation, the aggregate annual capacity of which is 166,000 tons. The important works at Piano d'Orta, Italy, is being enlarged to increase its production from 4000 to 10,000 tons. In France, the Société Française des Produits Azotés is producing 4000 tons per year at its work at Notre Dame de Briançon. Other works of varying capacities exist in Italy, Switzerland, Germany and England.

THE INDUSTRY IN AMERICA

The American Cyanamid Company, with offices at 100 Broadway, New York City, is the exclusive owner of the American rights for the manufacture and use of calcium cyanamide. The initial plant of this company is in course of construction at Niagara Falls, Ontario, and it is anticipated that production will begin early in the spring of 1909. Pending the completion of its plant, the company is filling orders with material imported from Norwegian works. On the basis of 10 per cent. nitrogen content, the initial capacity of the half-unit plant at Niagara Falls will be 20,000 tons per annum. This cyanamide will yield from 12 to 15 per cent. ammonia. It is the intention of the company to follow this plant with others as the demand requires.

The Niagara Falls plant will differ from some works now operating in Europe, in that it will make its product complete in-

stead of obtaining calcium carbide from outside sources. The price of the finished product will be the same as that of Chile nitrate; in Europe the prevailing price is from 5 to 10 per cent. less.

MANUFACTURE OF CYANAMIDE

In the manufacture of calcium cyanamide, calcium carbide is first made from coke and lime in an electric furnace. This product is then powdered, placed in closed retorts, and nitrogen, isolated from the air in the electric furnace, is led through it. This is the Frank & Caro process. The reaction between the carbide and the nitrogen is an exothermic one, and yields free carbon in the form of graphite, which remains distributed in the mass of material, giving it a black color. The equation for the formation of cyanamide from calcium carbide is as follows: $\text{CaC}_2 + 2\text{N} = \text{CaCN}_2 + \text{C}$. When lime and coke are employed as raw materials in place of calcium carbide, the reaction becomes: $\text{CaO} + 2\text{C} + 2\text{N} = \text{CaCN}_2 + \text{CO}$. This is a modification of the original process, on which Frank has secured a patent.

The carbide which will be manufactured by the American Cyanamid Company is expected to have about the following analysis: Nitrogen (expressed as ammonia) 12 to 15 per cent.; free carbon, 10 per cent.; calcium sulphate (land plaster), 25 per cent.; sulphides, phosphides and carbonate, 2 per cent.; iron oxide, 2 per cent. In deference to the requirements of the American trade, free lime is to be eliminated, and the nitrogen content reduced as compared with the foreign product.

Magnesite

The only important commercially utilized deposits of magnesite in the United States are in California, although small veins are found in Nevada, Arizona, Maryland, Massachusetts, and Pennsylvania. The California deposits are mainly in the Coast Range. Quite a number of deposits are known, but only a few are at present being worked; this is mainly due to the fact that the consumption on the Pacific coast is limited and that the material will not bear the cost of transportation to points in the Eastern States, where the magnesite must compete with that imported from Austria, Greece and South Africa. The domestic output, all from California, averages between 7000 and 8000 crude tons annually, worth at the points of production from \$3 to \$3.50 per ton. The present importations of crude and calcined magnesite to the United States amount in value to from \$850,000 to \$900,000 a year, and, of magnesite in the form of chemicals to between \$30,000 and \$40,000 a year. The largest quantity im-

ported comes in the form of calcined, but not purified magnesite. To make one ton of calcined material requires 2.4 tons of crude mineral. The calcined magnesite varies in value from \$12 to \$20 per ton according to the nature of the roast given the crude mineral. For the manufacture of brick, a much longer roast must be given than when the calcined mineral is to be used in the manufacture of paper from wood pulp, for which purpose most of the domestic material is utilized.

The use of magnesite in its various forms, but especially of the ordinary calcined magnesite, is increasing in the United States, as is shown by the heavier importations each year. The domestic output, however, varies but little, although more is now being used than formerly in making flooring, wainscoting, tiles, and other building material. Its use does not increase materially for furnace linings, as the imported material employed for that purpose can be obtained more cheaply than the domestic. The latter must be shipped from California by rail, while the imports all come by sea. The freight charges by rail are such that the California producers are unable to compete with the foreign at points where the largest consumption occurs. An effort is being made to induce Congress to impose a duty on foreign magnesite, but it is doubtful if this will be accomplished as the domestic producers are so few and the consumers are so many in number. Many deposits in California which are idle and undeveloped would be worked were there any hopes of finding a profitable market for the material. As it is, the few which are being worked are close to lines of transportation and are operated mainly in the interest of the manufacturers of paper from wood pulp or of liquid carbon dioxide.

Only two new deposits became productive in 1908, the one at South Tule in Tulare county, virtually owned by the Williamette Pulp and Paper Company, the other near Winchester, Riverside county, owned by the California Magnesite Company. At the Williamette company's mine, a calcining furnace was erected during 1908, and all the material produced is shipped in the form of calcined mineral, going direct to the pulp mills of the paper company. The deposit at Winchester furnished some material which is utilized in Los Angeles for manufacture of flooring, tiles, drain-boards, wainscoting, etc.

The most important producing mine in California continues to be the mine at Porterville, Tulare county, which is leased by the Williamette Pulp and Paper Company, and superintended by W. P. Bartlett. This mine is fully described, as are its calcining works, in Bulletin No.

355 U. S. Geol. Surv., by Frank L. Hess. For some years by far the largest proportion of the output of California has come from this mine. A few hundred tons per year are mined from the deposits at Cloverdale, Sonoma county, and at Red Mountain, Alameda county. Aside from the magnesite deposits mentioned, little or nothing is being done with the other known deposits of the State. There are now several factories in California which make different forms of building material from the domestic product.

The manufacturers of carbonic acid gas, who market a liquid carbon dioxide, after calcining the material to obtain their product, dispose of the magnesia residue to the paper mills, where it is changed to a sulphite and used in the digestion and whitening of wood pulp for paper.

Phosphate Industry in Tennessee

By H. D. RUHM*

The situation in the Tennessee phosphate field during 1908 was fairly well predicted in these columns a year ago when I said "the only possible salvation of the situation as to present prices is in the policy of curtailing production, and, unless the miners get together and consolidate in some way, their thrift is short for the maintenance of recent prosperity."

No such consolidation was effected, and in the meantime the manufacturers increased the efficiency of their mining organizations to such an extent that they now seem amply able to take care of their own needs for several years to come.

This almost entirely cut out the selling of rock on the domestic market, and, with the exception of a few old contracts and a few new sales (mostly for export), shipments in 1908 were largely confined to the operations of the Virginia-Carolina Chemical Company (Charleston Mining and Manufacturing Company), the Federal Chemical Company, the American Agricultural Chemical Company and the Independent Phosphate Company with its allied interests. The shipments from points in Tennessee on the Louisville & Nashville railroad for the years 1905 to 1908, inclusive, are given below in short tons:

Year.	Domestic.	Export.	Total.
1905	285,321	110,407	395,728
1906	379,894	110,511	490,405
1907	329,686	102,996	432,682
1908	320,634	81,123	401,757

While the drop in production was sudden and startling from the high-water mark of 1907, it is still above 1905, showing that, even with all the depression in

*Metallurgical and mining engineer, Mount Pleasant, Tenn.

financial circles, shipments still exceeded the 400,000-ton mark, which has come to be considered the normal amount of rock that the Tennessee field should legitimately supply to the territory dependent upon it.

However, as the large bulk of this phosphate rock was mined and shipped by manufacturers for their own consumption, it can well be understood that 1908 was a very lean year for the miners and producers of rock who are dependent upon the sale of their output on the general market. During the year there was a marked falling off in prices. In September, 1907, the prices were for 72 per cent. domestic, \$5.25; for 75 per cent. domestic, \$6.25; for 78 per cent. domestic, \$7; 75 per cent. export, \$6.75; 78 per cent. export, \$7.50, f.o.b. mines. In September, 1908 (for what few sales could be made), the price ranged around 72 per cent., \$3; 75 per cent., \$3.50, and 78 per cent., \$4.50 for local buyers, with some small contract buying at from 25¢/50¢ in advance of above prices.

Very little phosphate rock was sold at these prices, however, so that during 1908 the principal diminution of available supply took place in the properties of the manufacturers. Since this condition is apt to be in existence for some time to come, it seems more than likely that the largest of the present producers will sooner or later be taken over by some one or other of the organizations representing the manufacturers, so that the ideal condition bids fair to come about when all the mining will be done by manufacturers for their own use, just as most of the iron ore is mined by the steel companies.

This will enable a regular tonnage output to be depended on, making it possible to solve many problems which, on account of the intermittent character that the business has always assumed, have not presented hitherto an easy solution.

The Independent Phosphate Company under the management of T. C. Meadows made a considerable reduction in the cost of output in comparison with that of 1907, so that after paying sinking fund, interest, and providing a surplus, it paid a 10-per cent. dividend on the basis of \$3.60 per ton for rock containing 73 to 75 per cent. calcium phosphate.

The organization of the Independent Fertilizer Company was announced during November, 1908, its officers are reported to be Waldemar Schmidtman, president; T. C. Meadows, vice-president and general manager; J. H. Carpenter, treasurer. It is understood that this company has obtained control of most of the independent fertilizer companies in the United States.

This company will undoubtedly be in a more satisfactory position than any other fertilizer company in the country. Through Mr. Schmidtman, it controls enormous potash deposits in Germany, and through Mr. Carpenter and Mr. Meadows

it controls the output of the present phosphate mines of the Independent Phosphate Company, the Richland Phosphate Company, the American Phosphate Company, the Middle Tennessee Phosphate Company, T. C. Meadows & Co., the Mount Pleasant Dryer Company, Ruhm & Gregory, France & Co., the International Phosphate Company and the pyrites mines at Pylriton, Ala.; through Mr. Meadows it also controls the sulphuric-acid output of the Tennessee Copper Company. With the advantages derived from these sources of raw materials the new organization will undoubtedly be able to manufacture fertilizer from \$2 to \$3 per ton cheaper than anyone else in the business, so that it can furnish the farmer with goods at the same prices as do the other manufacturers and still make a handsome margin of profit over its competitors.

During 1908 the Swan Creek railroad to the Mayfield mines of the Virginia-Carolina company was completed, and that company began supplying a large number of its factories with their blue phosphate which is said to be much superior to the Florida pebble rock, and almost as good as the high-grade Mount Pleasant rock.

The Independent Phosphate Company completed its railroad to Estes Bend and has the machinery on the ground for its plant there. The railroad to Leatherwood starts from Nashville; enough grading has been completed to warrant the expectation that the company will commence operations at Leatherwood by June 1, 1909.

The Middle Tennessee Phosphate Company completed its washer during 1908, and now has one of the best washing and drying plants in the field. The Blue Grass Phosphate Company completed its second washer and dryer, and the Jackson Phosphate Company got its dryer in operation. T. C. Meadows & Co. completed their drying plant and have all machinery ordered for the washer. The Federal Chemical Company is installing washers of improved construction at both the Century and Tennessee branches. The Richland Phosphate Company's drying plant was completed and plans for a washer are under consideration.

The Columbian Phosphate Company, after having paid 10-per cent. dividends every six months for a number of years finally worked out to the point where it was not desirable to maintain a separate organization, so it was taken over by the Petrified Bone Mining Company, an affiliated concern. Both the Maury Phosphate Company and France & Co. have plans under consideration for a washer and dryer.

A new organization known as the Franco-American Phosphate Company has under option a large amount of undeveloped phosphate property and one going concern, the Volunteer Phosphate Company, of Centerville; it is said that this company plans to build two large plants.

The demand for phosphate properties is

decidedly strong, and owners of phosphate land are still holding at high prices, although considerably lower prices prevail than were asked in 1907.

The most noteworthy development of the phosphate business during 1908 was the marked tendency to use washers for preparing all grades of rock for market. In the first stages of the phosphate business, washers were extensively used, but as the method of recovery was over screens entirely, and as nothing was recovered smaller than the oversize from screens having $\frac{1}{4} \times \frac{3}{8}$ -in. openings, it was found not only that an enormous percentage of the rock itself was ground up by the logs and screens and carried off with the waste into the settling ponds, but also that a considerable percentage of the clay formed into balls and went with the phosphate oversize from the screens. This clay, which baked into hard lumps during drying, not only decreased the resulting percentage of bone phosphate, but also increased the amount of deleterious iron oxide and alumina in the rock.

The first departure was to abandon all the machinery and to return to the old-fashioned method of simply drying in kilns on cordwood. As the mining progressed and more effort was made to save the portion of the deposit formerly wasted, mechanical dryers of the cylindrical type were brought into use and the entire deposit saved. In this method the rock was also badly pulverized, and much of it was lost with the screenings when the making of high-grade rock was attempted. By screening or by proper selection in the mine, the entire product of the dryer can be saved, but it is of only an average grade, still having a considerable amount of the clay, while a large amount of rock is left in the rejects, or in the waste bank.

Producers then set about designing machinery that would save all of the rock and eliminate all of the dirt, with the result that practically everyone has turned to the combination of washers and dryers, the finest grains of phosphate being recovered by settling in water. It has been demonstrated that the very fine granules can be concentrated so as to contain 75 per cent. or better in phosphate of lime, and that by this method the saving is nearly double that made with the old wasteful method.

The best results so far have been obtained by the Federal Chemical Company which has perfected methods to the point where it has felt justified in spending many thousand dollars in the erection of plants to do this work. The method consists in washing the lump rock over drag conveyers, with hose pipes, passing the small pieces and clay through submerged screens and then through pug mills; by this method the small clay balls are entirely eliminated. The fine waste and water is then pumped into a series of settling tanks from which the fine settlings are washed out and pumped into wet stor-

age bins; the water is then allowed to drain out for several hours, and finally the fine material is passed through cylindrical dryers.

The Charleston Mining Company uses log washers and passes the waste through hydraulic classifiers, the phosphate granules discharging at the bottom to the dryers and the clay passing out at the top to the waste ponds.

The Independent Phosphate Company and its allied companies are proceeding on a combination of the above principles, expecting to accomplish good results with a much smaller outlay of money.

The bad reputation achieved for Tennessee rock during the hurry-scurry methods of 1907 has been almost wiped out by the high-grade product shipped in 1908, and by another year it will be as easy to depend on getting uniform high-grade rock from Tennessee as it is now to get uniform low-grade rock from the Florida pebble district.

The use of Mount Pleasant raw pulverized phosphate rock for direct application to the soil and for mixing with barnyard manure received a great impetus during 1908, and more was shipped for this purpose than ever before. Farmers who have used phosphate rock in this manner for a number of years seem to get good results, and this may prove an outlet for the producer not connected with the fertilizer manufacturers.

Aluminum

The sole American producer, pursuing the stand-pat policy of the Steel Corporation, kept the price at 33c. until Oct. 1. Then the convention among the European producers expired, and there being a great excess of productive capacity in Europe and the accumulation of an immense unsold stock, active competition promptly and naturally developed, and the price fell to $1\frac{1}{2}$ @14c. The duty of 8c. per lb. on importation into this country was no longer a protection, and the American producer made successive reductions in its nominal price to 24c., which ruled at the close, but foreign aluminum could be had at 22c. The disruption of the European convention marked the appearance for the first time of aluminum as a commercial metal; not that it was not previously an article of large trade (the world's production in 1907 having been 32,500 metric tons), but previously it had not been an article of competitive buying and selling, like copper, lead, tin and the others. It is noteworthy also that in 1908 aluminum sold in Europe for less than copper, pound for pound.

The gold output of Rhodesia for September, 1908, was 48,573 oz., valued at £204,261.

Quicksilver

Reports from producers making about 75 per cent. of the production indicate approximately the same output in 1908 as in 1907. On this basis we estimate the production in 1908 at 20,000 flasks against 20,932 in 1907.

The average monthly prices of quicksilver are given in the accompanying tables.

The Dennis fine-ore furnace at Blackbutte, Oregon, is not yet in steady operation, and it is doubtful if it is adapted to large operations. In this furnace there are a series of hearths, the ore being dumped from one to the next lower. Producer gas is used for fuel, which is a desirable innovation, as no soot is produced.

The loss in the Czermak-Spirek fur-

a 30-ton Scott furnace. The shaft is said to be 300 ft. deep. There was no production. The ore contains copper, gold and silver, and the plan is to recover the mercury by a preliminary roast, treating the cinders subsequently for copper, gold and silver.

In Texas the main producers for the year were the Maria and the Mariposa mine, in Lower Cretaceous limestone, and the Chisos mine in the overlying Eagle-Ford shales. The Chisos is still using the Tigner 10-ton furnace, although a Scott furnace was completed in April at the mine.

The Texas-Almaden company at Big Bend has a deposit in an intrusive sheet of trachyte under which there was presumed to be shale. Diamond-drill borings through the trachyte have now penetrated the shale at a depth of 600 ft., and the cores are said to look encouraging. This company has a 20-ton Scott furnace, and made a small production in their first run.

AVERAGE MONTHLY PRICE OF QUICKSILVER.
(IN DOLLARS PER FLASK OF 75 LB.)

Quicksilver in 1908

By H. W. TURNER*

The larger part of the domestic production of quicksilver is consumed within the United States. Shipments to Mexico are small, and those to the Orient have practically ceased, since to compete with the Spanish product would reduce the price to a low figure.

Of the domestic consumption, most of the quicksilver is used in the manufacture of vermilion, of scientific instruments, and mirrors. The consumption for amalgamation of gold and silver ores is not large. It is estimated from careful records that not more than 2/10 oz. of mercury is used up in amalgamating the gold and silver of one ton of ore, and in the Alaska-Treadwell and some Mother Lode mines the amount is less. The amount now consumed in placer mining in the United States is not great, but in Alaska it must be considerable.

METALLURGY OF QUICKSILVER

During 1908 there were no improvements of note in quicksilver furnaces. The most popular furnace is the fine-ore tile furnace built by Robert Scott, although some modifications of this have been introduced at New Idria and Oat-hill. The term *fine-ore* is used here to include both *tierra* (fines) and *grancita* (medium) grades of ore, as both are usually worked together in the same furnace. Coarse-ore furnaces, differing in detail, are in use at several of the mines, as the Newcomb furnace at New Idria, and the Maxwell furnace at the Great Eastern.

naces in use at Monte Amiata, Italy, is given at 4 per cent. It is altogether probable that the losses in the best American furnaces is much more than this. Now that the grade of ore treated is becoming lower, year by year, it would appear that the subject of furnace losses should receive the attention of a competent metallurgist.

Oil fuel is used at New¹ Almaden, but at New Idria its use has been discontinued, as at the present price of oil, wood fuel from the neighboring forest reservation is cheaper. Coke is used in the Neate coarse-ore furnaces at the St. John's. These are shaft furnaces, the coke and ore being charged in alternate layers.

CALIFORNIA

As usual, California produced the larger part of domestic quicksilver. Although many of the smaller mines were closed down, the production exceeded the demand. Notwithstanding this, prices were good. The main producers for the year were the New Idria, Napa Consolidated, New Almaden, Great Western, Helen and St. John's, with some production from the Guadalupe and the Oceanic.

At the Culver-Baer in Sonoma county a good orebody was developed, and a Scott furnace is to be erected. At the Karl mine in San Luis Obispo county, orebodies are being developed and the condensing system improved.

OTHER STATES

The new Dennis furnace at Blackbutte, Oregon, was fired up in February and soon after closed down. The Colonial company at Ehrenberg, Arizona, erected

FOREIGN COUNTRIES

Wm. Fleet Robertson, provincial mineralogist, reports that none of the prospects in British Columbia have as yet developed into working mines.

In Mexico the main production is at the Huizucoc mine in Guerrero, using a continuous furnace designed by J. W. C. Maxwell. The ore contains antimony.

At the Monte Amiata mines, Italy, the cost for mining and smelting was about \$5 per ton. In the Czermak-Spirek fine-ore furnace, the loss of the mercury is claimed to be only 4 per cent.; if true this is probably a record saving. A cinabar deposit was found near Pereta and opened up to some extent by shafts.

In 1907, according to Rogovin, the only mines producing in Russia were those of the Bachsmut district, the product being 8055 poods, equal to about 3879 flasks of 75 lb. each.

Quicksilver ore is reported from two new localities near Spizza in Dalmatia, Austria, but the deposits do not appear to be important.

The rediscovered mines of Koniah, Asia Minor, were reported on by F. F. Sharpless and F. P. Monaci. The ore is found in limestone accompanied by secondary silica, and in part associated with stibnite. The ore averages more than 1 per cent. mercury, and is treated in a 15 Spirek shaft furnace and in an eight-ton Czermak-Spirek fine-ore furnace. These were in continuous operation since May, 1906.

Monaci states that at the Kara Bornu mine, near Smyrna, there is a quicksilver deposit of sufficient size to be quarried so that 0.25 per cent. ore is profitable. In the year 1906-7 3000 flasks were produced.

*Geologist and mining engineer, San Francisco, Cal.

THE MINING INDEX

The editors of this paper read all the important publications of the world that relate to mining and the treatment of minerals. This index is published as a reference for all interested and to make it impossible for readers of the **ENGINEERING AND MINING JOURNAL** to miss any important article published anywhere.

We will undertake to furnish a copy of any article (if in print) in the original language, for the price quoted. Where no price is quoted the cost is unknown. These papers are not kept in stock, but must be ordered from the publisher; hence there will be some delay for foreign papers.

No accounts can be opened for these small amounts, but remittance must be sent with order. For the convenience of those making small but frequent remittances, coupons are furnished at the following prices: 20 cents each, six for \$1.00, thirty-three for \$5.00 and one hundred for \$15.00. This arrangement will be especially appreciated by foreign readers and men in distant mining camps. Where remittances are made in even dollars we will return the excess over an order in coupons upon request.

ALUMINUM

8172—BRITISH ALUMINUM COMPANY—The Kyaukse Works of the British Aluminum Company. (Electrician, Dec. 4, 1908; 5 pp.) The works of this company are described together with auxiliary apparatus and equipment. Illustrated. 40c.

8173—USE FOR ELECTRICAL PURPOSES—Aluminum as a Factor in the Electrical Industry. (Electrician, Nov. 27, 1908; 1½ pp.) Discusses briefly the preparation and uses of aluminum and compares the physical properties of aluminum and copper wires. 40c.

8174—USES—Aluminum and Some of Its Uses. J. P. W. Echevarri. (Min. Journ., Nov. 14 and 21, 1908; 2 pp.) Paper before the Brit. Inst. of Metals. Describes physical and chemical properties, methods of working and application by manufacturers. 60c.

CEMENT

8175—GERMAN MILL—Electric Driving of a German Portland Cement Mill. Alfred Gradewitz. (Electrical Rev., Dec. 26, 1908; 2½ pp.) Gives a description of one of the largest and most interesting German cement works in which electric drive has been recently adopted. The works are known as the Rüdgersdorf Portland Cement Fabrik. Illustrated. 20c. 20c.

8176—MICROSCOPIC STUDY—Ueber Mikrographische Zementuntersuchung. Ernst Stren. (Stahl u. Eisen, Oct. 21, 1908; 6¼ pp.) Describes methods pursued and gives some actual results in study of the structure of hardened cement by the microscope. 40c.

8177—PORTLAND CEMENT—Free Lime in Portland Cement. A. H. White. (Journ. Ind. and Eng. Chemistry, Jan. 1909; 5½ pp.) Describes tests for determining the amount of free lime in portland and other commercial cement and describes also the microscopic method of testing cement. Illustrated. 60c.

8178—PORTLAND CEMENT—Manufacture of Portland Cement from Materials High in Magnesia. Richard K. Meade. (Cement Age, Dec. 1908; 3¼ pp.) Discusses the effect of magnesia upon the properties of portland cement and suggests the addition of calcium chloride as a retarder. 20c.

8179—PORTLAND CEMENT—The Effect of Magnesia on Portland Cement. Rudolph Dyckerhoff. (Cement Age, Dec. 1908; 4 pp.) This is a translation by R. K. Meade of the paper by Dr. Dyckerhoff and gives a number of experiments on cement materials high in magnesia. The results indicate that 5 or 6 per cent. of magnesia are not detrimental. 20c.

8180—PROGRESS IN THE CEMENT INDUSTRY—Important Discoveries in the Lime and Cement Industries. H. S. Spackman. (Cement Age, Dec. 1908; 5 pp.) Describes tests on cements using calcium aluminate as an addition to hydrated lime and argillaceous or siliceous material. 20c.

COAL AND COKE

8181—ACCIDENTS—Fatal Accidents in Coal Mines of America. F. L. Hoffman. (Eng. and Min. Journ., Dec. 19, 1908; 4 1/3 pp.) Shows statistically how more

than 3,000 persons were killed in coal mining operations in 1907 and how 20,000 lives have been lost during the last decade. 20c.

8182—AUSTRALIA—Coalfields and Collieries of Australia. F. D. Flower. (Aust. Min. Stand., Oct. 7, 14, Nov. 4 and 11, 1908; 11 pp.) Continuation of article previously indexed. 60c.

8183—CANADA—The Mining Operations of the Dominion Coal Company. F. W. Gray. (Can. Min. Journ., Dec. 1, 1908; 4½ pp.) Describes the operation and development of this company's No. 2 colliery, including a brief description of the central electric plant and the central hospital. Illustrated. 20c.

8184—CHARCOAL—Tests with Car Kilns. Evert Norlin. (Jernkontoretts Annaler, Nov., 1908; 44 pp.) Describes test runs and experiments for the determination of the heat conditions and the output of charcoal and by-products of car kilns of the American type. 20c.

8185—COAL CUTTING in Northern Coalfield, England. George R. Dixon. (Eng. and Min. Journ., Dec. 5, 1908; 1½ pp.) Mining machines have increased the earning power of the men and have made their work less arduous. Compares the cost of mining. Illustrated. 20c.

8186—COAL DUST—British Coal-Dust Experiments. (Mines and Minerals, Dec. 1908; 1½ pp.) Describes an experimental gallery erected at Altofts and gives the results of 26 experiments with coal and stone dust. Illustrated. 20c.

8187—COAL DUST—Recent Demonstration of Coal Dust Phenomena. James Ashworth. (Coll. Guardian, Dec. 11, 1908; 1 p.) A paper read at a recent meeting of the North Staffordshire Institute of Min. and Mech. Engineers. Discusses at present explosion as to whether it was caused by gas or coal dust. 40c.

8188—COKE—Jones and Laughlin's Coke Plant. W. A. Affelder. (Mines and Minerals, Dec., 1908; 4½ pp.) Describes the installation of 1600 coke ovens in the closely built part of the city of Pittsburgh. Illustrated. 20c.

8189—COLORADO—Routt County. Colorado. Coals. R. L. Herrick. (Mines and Minerals, Dec. 1908; 4½ pp.) Describes the location, geology, mines opened, different qualities of coal, thickness of seams, transportation and possible markets. Illustrated. 20c.

8190—COMPOSITION—Coal: Its Composition and Combustion. W. H. Booth. (Colliery Guardian, Dec. 11, 1908; 1½ pp.) Discusses the heat of combustion of carbon and hydrogen and various characteristics of coal, considering only chemical composition and combustibility. Illustrated. 40c.

8191—ELECTRICITY in Modern Coal Mining. Harvey J. Nelms. (Eng. and Min. Journ., Dec. 5, 1908; ¾ pp.) Gives certain precautions which should be adopted when electric power is used underground. 20c.

8192—ENGLISH COLLIERY—Notes on a Yorkshire Colliery. L. C. Ball. (Queens. Govt. Min. Journ., No. 14, 1908; 2¼ pp.) Gives a brief description of the general design, the geology, method of working and the washery of the Cadeby colliery, located in Yorkshire. 60c.

8193—EXPLOSION—Facts Concerning the Marianna Explosion. Floyd W. Parsons. (Eng. and Min. Journ., Dec. 12,

1908; 4½ pp.) The fan indicator diagram shows that ventilation stopped 25 minutes before the explosion. It is claimed that the clock was slow. Gives methods of mining and ventilating this mine in which such a large loss of life occurred on November 23, 1908. Illustrated. 20c.

8194—EXPLOSIONS—Dust as a Factor in Mine Explosions. William N. Page. (Eng. and Min. Journ., Dec. 5, 1908; 1½ pp.) Paper before the W. Va. Min. Assn. The author believes watering coal mines is apt to be dangerous and recommends that air currents be split and auxiliary fans used. 20c.

8195—EXPLOSIVES—Safety Blasting Explosives. A. M. Comey. (Mines and Minerals, Nov., 1908; 4 pp.) Classes and properties of different explosives. Apparatus and methods used in testing. Illustrated. 20c.

8196—MINE SAMPLING and Chemical Analyses of Coals Tested at the United States Fuel Testing Plant in Norfolk, Va., 1907. J. S. Burrows. (Bull. No. 362, U. S. Geol. Surv., 23 pp.) Describes the tests of coals taken from Jamestown beds Nos. 1 to 17 inclusive. Gives chemical analysis of the coals sampled in the mine and in the car. 20c.

8197—MINING METHOD—Coal Mining on the Retreating System. Harvey J. Nelms. (Eng. and Min. Journ., Dec. 26, 1908; ¾ pp.) Describes the general system of working on the retreating room-and-pillar plan which insures the operator of a greater amount of coal than when the seam is worked advancing on the room-and-pillar system. Illustrated. 20c.

8198—OKLAHOMA—The Coal Resources of Oklahoma. C. N. Gould. (Min. Wld., Dec. 12, 1908; ¾ pp.) Discusses the value of Oklahoma's coal resources and describes the conditions in the district and the more important ledges. Illustrated. 20c.

8199—RESCUE WORK—The Mining Operations of the Dominion Coal Company. F. W. Gray. (Can. Min. Journ., Nov. 15, 1908; 5½ pp.) Continuation of article previously indexed. Describes the fire fighting organization and equipment of the Dominion Coal Company. Illustrated. 20c.

8200—SIAFT—Enlarging a Shaft Without Cessation of Working. M. Brien. (Min. Eng., Dec., 1908; 3½ pp.) Describes the method of enlarging No. 5 shaft of the Aggrape colliery between the 290m. and 380m. levels without interfering with the hoisting. Illustrated. 20c.

8201—WASHERY—The Operation of a Coal Washery in Colorado. W. F. Murray. (Eng. and Min. Journ., Dec. 26, 1908; 3 pp.) Describes the construction and method of operation including an aerial tramway used to dispose of waste. Illustrated by working drawings. 20c.

8202—WEST VIRGINIA—Coal Fields of West Virginia. H. H. Stock. (Mines and Minerals, Dec., 1908; 3 pp.) Geology of the region, transportation routes, description of the coals with analyses from different seams. Illustrated. 20c.

COPPER

8203—ALASKA—Copper Deposits of White Horse. T. A. Rickard. (Can. and Sci. Press, Dec. 5, 1908; 1½ pp.) De-

scribes some of the copper claims in this Alaskan district. Illustrated. 20c.

8204—ALLOYS.—Copper and Copper Alloys. J. T. Milton. (Iron Age, Dec. 11, 1908; 3 pp.) Discusses failure in copper tubes, annealing conditions, corrosion of copper and its alloys, the structure of copper alloys, gun metal and white metals, etc. From a paper read before the Brit. Institute of Metals. 20c.

8205—ANALYTICAL METHOD.—Permanganate Method for Determining Copper. Fred G. Hawley. (Eng. and Min. Journ., Dec. 12, 1908; 3/4 pp.) This method, which is used in the assays of the Cananea Consolidated Copper Company gives satisfaction where quick results are required and many determinations are to be made. It ranks with the iodide method for accuracy. 20c.

8206—CALIFORNIA.—The Blue Ledge Copper Fields. A. H. Martin. (Min. Sci. Dec. 24, 1908; 1 1/4 pp.) Describes the copper properties in this district of Siskiyou county and gives analysis of the ore. 20c.

8207—COSTS.—Calumet and Hecla Costs—L. L. S. Austin. (Min. and Sci. Press, Dec. 19, 1908; 1 3/4 pp.) Describes the conditions existing at the Calumet and Hecla mine, and gives costs of working the Osoyoos amygdaloid lode in 1906. The actual cost of producing a pound of copper is not given. 20c.

8208—ELECTROLYTIC COPPER.—Influenza Dell'essigno Nascante Sulla Deposizione Elettrolica del Rame. Corrado Agnolucci. (Rassegna Mineraria, Nov. 1, 1908; 2 1/4 pp.) Discusses the effect of nascent oxygen on the electrolytic deposition of copper. 40c.

8209—LABORATORY ROUTINE in Modern Copper Smelters. H. T. Waller. (Inst. Min. and Met., Nov. 12 and Dec. 10, 1908; 7 pp.) Discussion and contributed remarks on the above paper by members, in which additional information is given.

8210—MINE WATERS. Alfred C. Lane. (Proc. Min. and Met. Inst., June, 1908; 90 pp.) This is an elaborate treatise on the constitution of mine waters from the copper mines of Michigan. Illustrated.

8211—NEVADA.—Mining and Reduction of Zinc. R. L. Herrick. (Min. and Minerals, Nov. 1908; 5 1/2 pp.) Continuation of article. Describes the concentrator site and construction, methods of concentrating and smelting, power plant and costs. Illustrated. 20c.

8212—SLAGS.—Alumina in Copper Blast Furnace Slags. Charles F. Shelby. (Eng. and Min. Journ., Dec. 26, 1908; 1 1/2 pp.) Discusses the article by H. E. Hooper in the Journal of December 5 and contributes additional information on the subject. 20c.

8213—SMELTING at Cerro de Pasco, Peru. L. W. Strauss. (Min. and Sci. Press, Nov. 7, 1908; 7 1/2 pp.) Describes the method of smelting the ore at this smelter which is at an altitude of 14,000 ft. above sea level. Describes also the sampling plant and the furnace charges together with the analyses of the ore, matte, slag and flue dust. Illustrated. 20c.

8214—TENNESSEE.—Mining and Smelting in the Ducktown District. Edwin Higgins. (Eng. and Min. Journ., Dec. 26, 1908; 4 1/4 pp.) Describes the methods of mining and smelting at the Tennessee Copper Company's plant at Copperhill. The ore which averages 2 per cent. copper occurs in great lenses in metamorphic schist. Describes the sulphuric acid plant. Illustrated. 20c.

8215—UTAH.—Ore Occurrence at Fortuna Mine. E. R. Zaluski. (Eng. and Min. Journ., Dec. 19, 1908; 4 1/2 pp.) Describes the geology, the vein system, character of ore, secondary enrichment, the impregnated quartzite together with a description of the Fortuna and Mayflower veins. Illustrated. 20c.

GOLD AND SILVER

8216—AMALGAMATION METHODS. H. W. MacFarlane. (Min. and Sci. Press, Dec. 12, 1908; 2 3/4 pp.) Discusses the care of plates, the use of amalgamators and the treatment of ore by amalgamation. 20c.

8217—AUSTRALIA.—Wallahalla and District Mines, Victoria. (Aust. Min. Stand.,

Nov. 11, 1908; 2 1/2 pp.) Describes the geology and the workings of the Wallahalla mines and gives a flow sheet of the Long Tunnel Gold Mining Company. Describes also the mining outside of the Wallahalla district proper. 40c.

8218—CALIFORNIA.—The Callico Gold Mine. W. H. Stornis. (Am. Min. Rev., Nov. 21, 1908; 2 1/4 pp.) Describes the peculiar occurrence of a belt of gold ore, diagonally connecting two veins of silver ore. Illustrated. 20c.

8219—CALIFORNIA.—The Success of the Orange Blossom Extension. Will C. Higgins. (Salt Lake Min. Rev., Nov. 30, 1908; 4 pp.) Describes the geology, operation and equipment of the mine and mill of the Orange Blossom Extension M. and M. Company which is operating claims in San Bernardino Co., Cal. 20c.

8220—COLORADO.—The San Juan Region. Conrad and H. T. R. Reed. (Min. and Sci. Press, Nov. 7, and 14, 1908; 9 pp.) Describes the history, the mines, and methods of treating the ore of this district. Illustrated. 40c.

8221—COMSTOCK LODGE.—Decline and Revival of Mining. J. H. G. Wolf. (Min. and Sci. Press, Nov. 7, 1908; 2 pp.) Comments on a previous article by W. Symmes, and gives additional information, together with statistics of production, etc. 20c.

8222—COMSTOCK LODGE.—Progress on the Comstock Lode. R. L. Herrick. (Min. and Minerals, Nov., 1908; 5 1/4 pp.) Difficulties which caused cutting down, engineering and other advantages that have aided the reopening. Illustrated. 20c.

8223—CYANIDATION of Silver Ores. W. A. Caldecott. (Min. and Sci. Press, Dec. 12, 1908; 1 p.) A discussion of J. H. Jones's article on this subject. Additional information is advanced and a number of reactions are given. 20c.

8224—CYANIDE PLANT.—Home-Made Cyanide Plant. W. F. Boericke and B. L. Eastman. (Min. and Sci. Press, Nov. 21, 1908; 3 1/2 pp.) Describes a simple cyanide plant which treats at a profit low-grade tailings, formerly thrown away, and which was built by two men at small cost of labor and supplies and a trifling initial expenditure. 20c.

8225—CYANIDING SLIME. E. B. Wilson. (Min. and Minerals, Nov. Dec. 1908; 61 pp.) Continuation of article previously indexed. Describes the Moore and Butters' vacuum filters, the arrangement of the plants, construction and operation of the machines. Illustrated. 40c.

8226—DREDGING on the Seward Peninsula. T. A. Rickard. (Min. and Sci. Press, Nov. 28, 1908; 7 pp.) Describes the progress in dredging the auriferous sands of the Seward peninsula. Gives cost and other valuable data. Illustrated. 20c.

8227—GOLD DREDGING in California. (Eng. and Min. Journ., Dec. 12, 1908; 3 1/2 pp.) Briefly describes the progress in gold dredging and improvements in dredges and gold savers. 20c.

8228—HYDRAULIC MINING.—Examining and Fitting up a Hydraulic Mine—L. H. A. Brigham. (Eng. and Min. Journ., Dec. 26, 1908; 3 1/2 pp.) This is an abstract of information already before the Technical Society of the Pacific Coast. Methods of examination and the placing of pipe lines, receiving reservoirs, drain tunnels and sluices are discussed in this installment. 20c.

8229—HYDRAULIC MINING.—Practical Methods of Examining and Fitting up a Hydraulic Mine. L. H. A. Brigham. (Journ. Assn. Eng. Soc. Oct. 1908; 50 pp.) Discusses preliminary and detailed examination, water supply, pipe lines, plant of installation, sluices, drains, plants, hydraulic elevators, ditches and flumes, etc. 40c.

8230—MEXICO.—Hostotlaquillo and the Lirios River. Ezequiel Ordonez. (Min. and Sci. Press, Nov. 21, 1908; 3 1/2 pp.) Describes the conditions existing in this mineral portion of the district of Tequila of the State of Jalisco. Illustrated. 20c.

8231—MEXICO.—Mining on the Setenon. Mark R. Lamb. (Min. and Sci. Press, Dec. 19, 1908; 2 1/2 pp.) Describes a visit to the mines and prospects in this Mexican district in Chihuahua. Illustrated. 20c.

8232—MINING METHODS in the North. —I. T. A. Rickard. (Min. and Sci. Press, Dec. 12, 1908; 4 pp.) Discusses condi-

tions existing in the far North and the methods of handling gold-bearing gravel and extracting the gold therefrom. Illustrated. 20c.

8233—NEVADA.—A Scientific Search for a New Goldfield. Robert T. Hill. (Eng. and Min. Journ., Dec. 12, 1908; 3 pp.) By a study of ore occurrence at Goldfield and of the fault systems of Nevada a new alumite and gold district was discovered. Illustrated. 20c.

8234—NEVADA.—Camp Alumite. A New Nevada Gold District. R. T. Hill. (Eng. and Min. Journ., Dec. 19, 1908; 3 pp.) Describes the discovery of a new camp in Lincoln county, situated and mineralized like the Goldfield district and having similarly altered rocks. Illustrated. 20c.

8235—NEVADA.—Ore Deposits of De La Mar. W. R. Wardner. (Am. Min. Rev., Oct. 24, 1908; 1 p.) Describes the gold mines of De La Mar, Nevada with their faults, dikes and peculiarities. Illustrated. 20c.

8236—NEVADA.—Present Conditions at the Famous Comstock Mine, Nevada. A. H. Martin. (Min. Sci. Dec. 3, 1908; 1 1/4 pp.) Gives an account of the operations and methods employed at this old producing mine and discusses its future prospects. Illustrated.

8237—NEVADA.—The Goldfield Type of Ore Occurrence. Robert T. Hill. (Eng. and Min. Journ., Dec. 5, 1908; 3 1/2 pp.) Describes the country rocks, strikes and structure, the ores and ore occurrence and character of the ores, fumarolic action, aspects of the altered and mineralized rocks and the mineral alumite. Illustrated. 20c.

8238—NEW MEXICO.—Sylvanite, New Mexico, the New Gold Camp. Fayette A. Jones. (Eng. and Min. Journ., Dec. 5, 1908; 3 pp.) The Hachita range has been worked for turquoise, lead and copper, the tellurium-gold ores being until recently overlooked. Illustrated. 20c.

8239—NEW ZEALAND.—The Blackwater Mine, Inangahua County. Frank Reed. (N. Z. Mines Rec., Oct. 16, 1908; 1 1/2 pp.) Describes the geology, mining operations, reduction works and the results of treatment including a flow sheet showing the order of treatment of the ore when the works are completed. 40c.

8240—NEW ZEALAND.—The Future of New Zealand's Alluvial Goldfields. (Min. Journ., Nov. 21, 1908; 1 1/2 pp.) Describes the available ground and its value, methods and machinery and the personal factor which affects the industry. Illustrated. 40c.

8241—PATIO PROCESS. C. F. Duarte. (Journ. Chem. Met. and Min. Soc. of So. Africa, Oct. 1908; 4 1/2 pp.) Describes the theory and practice of the old Mexican amalgamation process. 60c.

8242—PERU.—San Antonio de Poto Hydraulic Mine, Peru. W. E. G. Firebrace. (Min. and Sci. Press, Dec. 2, 1908; 2 pp.) Describes an old and famous placer mine discovered in 1553 and which is still producing gold. Illustrated. 20c.

8243—PLACER DEPOSITS.—The Hand Drill in Prospecting Placer Deposits. John P. Huttnig. (Eng. and Min. Journ., Dec. 12, 1908; 4 1/2 pp.) Methods of drilling, especially with rotation of casing, and the advantages and disadvantages as compared with steam-drill prospecting. Illustrated. 20c.

8244—SMELTING.—Copper-Gold Smelting at Magistral, Robert Linton. (Min. and Sci. Press, Dec. 19, 1908; 3 1/4 pp.) Describes the smeltery at Santa Maria del Oro, Durango, including the charges used in the furnace. Illustrated. 20c.

8245—STAMP MILLS.—Some Notes on the Gravitation Stamp Mill. R. C. Robinson. (Queensland Gov. Min. R. C. Robinson, Oct. 15, 1908; 2 1/2 pp.) Discusses stamp mills, mill sites, general design and construction of mills including foundations, batteries and their accessories and certain metallurgical problems. 60c.

8246—STAMP MILLS.—Some of the Large Stamp Mills of the World.—H. Charles C. Christensen. (W. Min. Nov. 28, 1908; 2 pp.) Describes the construction and operation of the Homestake mills in South Dakota in which there are 1000 stamps. Gives data on the water supply, repairs to the mills, consumption and waste of quicksilver, bullion clean-up, costs and profits. Illustrated. 20c.

8247—TASMANIA.—The Lisle Goldfield, Tasmania. W. H. Twelvetyres. (Aust.

Min. Stand., Oct. 14, 1908; 5 p.) Discusses the source of gold supply in this field, which has been worked continuously for more than 30 years. 40c.

8248—WEST AUSTRALIA—Yilgarn Goldfield, Cheriton's Reward. A. Montgomery. (Aust. Min. Stand., Oct. 7, 1908; 2 pp.) Discusses the geology and lodes of the district. 40c.

IRON AND STEEL

8249—ALABAMA—Iron Operations in Northeastern Alabama. Edwin Higgins. (Eng. and Min. Journ., Dec. 5, 1908; 4 pp.) The Clinton red hematites occur in comparatively thin seams; brown hematites are found in residual clays; ores require little flux. Illustrated. 20c.

8250—CANADA—A New Iron Ore Field in the Province of New Brunswick. J. E. Hardman. (Iron Coal Tr. Rev., Nov. 27, 1908; 2/3 p.) Briefly describes the geography, topography, discovery and the record of a number of bore holes. Abstract of paper before the Can. Min. Inst. 40c.

8251—DRY BLAST—Gayley's Invention of the Dry Blast. R. W. Raymond. (Eng. and Min. Journ., Dec. 19, 1908; 2 1/2 pp.) Mere condensation, as proposed by others, was not sufficient for the removal of moisture, solidification made the method practicable. Paper read before A. I. M. E., Oct. 2, 1908. 20c.

8252—FOUNDRY CUPOLA PRACTICE. (Iron Age, Nov. 19, 1908; 1 p.) Paper read before the Detroit Foundrymen's Association by W. E. Eiden, treating of the use of limestone, excessive blast and cupola mixtures. 20c.

8253—LAKE SUPERIOR—The Great Iron Fields of the Lake Superior District. Robert B. Brinsmade. (Min. Sci., Dec. 3, 1908; 3 pp.) Describes the geology, method of prospecting, sampling and assaying, surveys and records. Illustrated; to be continued. 20c.

8254—LAKE SUPERIOR—The Great Iron Fields of the Lake Superior District. Robert B. Brinsmade. (Min. Sci., Dec. 17, 1908; 1 1/2 pp.) Discusses the conditions and methods of mining on the Vermillion Range, Minnesota. Illustrated. 20c.

8255—LAKE SUPERIOR—The Great Iron Fields of the Lake Superior District. Robert B. Brinsmade. (Min. Sci., Dec. 24, 1908; 2 1/2 pp.) Continuation of article previously indexed. Describes the conditions existing on the Mesabi range including drainage, stripping and use of locomotives and steam shovels. Illustrated. 20c.

8256—MINING METHOD—Stripping Clinton Iron Ore in New York State. Edwin Higgins. (Eng. and Min. Journ., Dec. 12, 1908; 2 1/2 pp.) Twenty feet of overburden removed to mine 22-in. bed of ore waste bank carried 60 ft. high by means of conveyor system. Illustrated. 20c.

8257—MINNESOTA—Structures of the Mesabi Iron Ore. N. H. Winchell. (Proc. Lake Superior Min. Inst., June, 1908; 15 pp.) Describes the structures and peculiarities of the ore in the mines of the Mesabi range. Illustrated. 20c.

8258—ROLLING—Die Kalibrierung der Gleichschenkligen Winkelisen. C. Rademacher. (Stahl u. Eisen, Oct. 28, 1908; 3 pp.) A study of the mechanics of rolling angle iron. 40c.

8259—RUSTING—Ueber den Angriff des Eisens durch Wasser und Wässrige Lösungen. E. Heyn and O. Bauer. (Stahl u. Eisen, Oct. 28, 1908; 10 pp.) Discusses the conditions particularly as to moisture and carbonic acid, affecting the rusting of iron, and gives experimental results. 40c.

8260—SAMPLING—Standard Method for Sampling Cargoes of Iron Ore at Lower Lake Ports, 1907. Oskar Textor. (Proc. Lake Superior Min. Inst., June, 1908; 2 pp.) Gives the details of sampling which are required at the ports along the lower lakes. 20c.

8261—SAMPLING OF IRON ORES. L. S. Austin. (Proc. Lake Superior Min. Inst., June, 1908; 6 pp.) Discusses several methods of sampling and calls attention to the advantage of automatic sampling. 20c.

8262—STEEL CAR PLANT of the Bettendorf Axle Company. (Iron Age, Dec. 3, 1908; 7 pp.) Describes the method of

handling material and turning out the finished product at this large plant. Illustrated. 20c.

8263—STEEL PLANT—The New Steel Corporation Plant at Gary. (Eng. and Min. Journ., Dec. 26, 1908; 3 1/2 pp.) Gives a description of the largest steel plant in the world which handles material from iron ore to finished steel on the latest and most approved lines. 20c.

8264—STEEL TUBING—The Manufacture of Seamless Steel Tubing. (Iron Tr. Rev., Nov. 19, 1908; 6 1/2 pp.) A description of process and manufacturing seamless tubes from solid steel billets and plates with special reference to the making of the Shelby product by the National Tube Company. Illustrated. 20c.

8265—STEEL WORKS—New Steel Works in the United States. (Engineer, Nov. 20, 1908; 1 1/2 pp.) Describes the new plant of the Bethlehem Steel Company, known as the Saucon Works. Illustrated. 40c.

8266—TARIFF—Charles M. Schwab on the Tariff. (Eng. and Min. Journ., Dec. 26, 1908; 1 1/2 pp.) Evidence before the Tariff Commission of Ways and Means. Discusses the cost of steel rails in 1899; present cost of making rails; cost of rails abroad; prices of rails; profits in the steel trade; labor cost; export prices and bessemer and open hearth steel. 20c.

8267—TESTING—Different Methods of Impact Testing on Notched Bars. P. W. Hambro. (Instn. of Mech. Engrs., Nov. 1908; 47 pp.) Discusses the relative value of impact test with the ordinary tensile test. Illustrated.

8268—TESTING—The Resistance of Materials to Impact. T. E. Stanton and L. Bairstow. (Instn. of Mech. Engrs., Nov. 1908; 32 pp.) Gives the results of a research to determine the resistance of materials to impact. Illustrated.

8269—TRADE—The World's Export Trade in Iron and Steel and its Regulation. Harold Jeans. (Iron Coal Tr. Rev., Nov. 27, 1908; 2 1/3 pp.) Discusses the trade of the United States, Germany, Belgium, France, Russia, Austria, Spain and Great Britain in iron and steel, giving figures which relate to iron and steel in the crude form but not manufactured into machinery. 40c.

MAGNESITE

8270—CALIFORNIA—The Magnesite Deposits of California. Frank L. Hess. (Bull. No. 355, U. S. Geol. Surv., 1908; 67 pp.) This is an excellent treatise on the deposits of magnesite in California and in various countries. Discusses also the composition, general character, and use of magnesite and its by-products. Illustrated.

MANGANESE

8271—BRAZIL—Manganese Deposits of Morro de Mina, Brazil. Joaquim Lustosa and J. C. Branner. (Eng. and Min. Journ., Dec. 19, 1908; 2 pp.) The deposits of manganese in Brazil are extensive and important. They are nearly vertical and are easily and cheaply mined by open cuts. The productive capacity is said to be dependent only upon transportation facilities. Illustrated. 20c.

8272—INDIA—A Manganese Deposit in Southern India. R. O. Ahlers. (Instn. of Mech. Engrs., Bull. No. 39, Vol. 51, Nos. 12 and Dec. 10, 1908; 19 pp.) Describes an important source of manganese ore in the Bellary district, State of Sandur, together with the geology of the district. Contributed remarks of the paper by members of the institution are also given.

8273—INDIA—The Mode of Occurrence of Manganite in the Manganese-Ore Deposits of the Sandur State, Bellary, Madras, India. A. Ghose. (Manchester Geol. and Min. Soc., June 16, 1908; 10 pp.) Describes the geology and mode of occurrence of the manganese ore discovered by the author. Illustrated.

PETROLEUM

8274—CALIFORNIA—Preliminary Report on the Coalinga Oil District, Fresno and Kings Counties, Cal. Ralph Arnold and Robert Anderson. (Bull. No. 357, U. S. Geol. Surv., 1908; 142 pp.) Describes the geography, topography, geology, igneous rocks, the oil and oil fields, trans-

portation, oil companies and oil wells in the district. Illustrated.

8275—FRACTIONATION OF CRUDE PETROLEUM by Capillary Diffusion. J. E. Gilpin and M. P. Cram. (Am. Chem. Journ., Dec., 1908; 43 pp.) This paper contains much valuable data on the subject derived from experiments by the authors. 60c.

8276—PERU—The Petroleum-Bearing Zone of Northern Peru. V. F. Maesters. (Min. Journ., Nov. 21, 1908; 2/3 p.) Describes the geology and occurrence of petroleum in the Coastal Plain and mountainous regions of Peru. 40c.

8277—STANDARD OIL COMPANY—The Business of the Standard Oil Company. (Eng. and Min. Journ., Dec. 5, 1908; 1/2 p.) Contains a portion of the testimony given by John W. Archbold vice-president of the Standard Oil Company of New Jersey, before the referee in the case of the U. S. Government against the company. 20c.

8278—SURAHANY GAS AND OIL FIELDS. (Petrol. Rev., Dec. 19, 1908; 2 pp.) Give a review of this field for the years 1905-06 giving the number of bore holes and the production of the various companies operating in this field. 40c.

8279—TESTS OF OIL MIXTURES—A Comparison of the Calculated and Determined Viscosity Numbers (Engler) and Flashing and Burning Points in Oil Mixtures. H. C. Sherman, T. Gray and H. A. Hammerschlag. (Journ. Ind. and Eng. Chemistry, Jan., 1909; 3 1/2 pp.) Describes the experiments made to determine in typical cases the direction and extent of the differences between the calculated and determined viscosities and flashing and burning points in mixtures of heavy and light petroleum lubricating oils and of petroleum with sperm oil or with fatty oils. Illustrated by diagrams. 60c.

8280—TRANSPORTATION—Review of Statistical and Technical Facts Submitted to the President by the Commissioner of Corporations. L. H. Eddy. (Cah. Derrick, Aug.-Sept., 1908; 2 pp.) Contains information regarding cost of pipeline transportation, pipeline charges compared with rail charges, history and descriptions of pipelines, etc. 20c.

8281—WEST VIRGINIA—Oil Field at Elkwater, Va. Frank W. Brady. (Mines and Minerals, Dec. 1908; 2 1/2 pp.) Location of wells, history of their development, production and general conditions of the district. Illustrated. 20c.

PHOSPHATE ROCK

8282—BELGIUM—Mittellungen über den Phosphatbergbau Belgiens. Dr. Tietze. (Preuss. Zeit. f. B. u. A. S., Band 56, Heft 4, 1908; 18 pp.) Describes the geological conditions, the mineralogical composition and the methods of operating phosphate deposits in several parts of Belgium.

PRECIOUS STONES

8283—DIAMOND MAKING—Researches in Diamond Making. F. H. Mason. (Min. and Sci. Press, Dec. 5, 1908; 1 1/2 pp.) Discusses the recent progress in experimenting with apparatus used to make diamonds artificially. Illustrated. 20c.

8284—DIAMOND PRICES—The Great Premier: Will the Company Cheapen Diamonds? (So. African Min. Rev., Oct., 1908; 2 1/2 pp.) Discusses the effect of increased production upon the ultimate price of diamonds. Gives cost of producing at the Premier and De Beers mine. Illustrated. 40c.

8285—JADEITE—Jadeite in the Kachia Hills, Upper Burma. A. W. G. Bleeker. (Ind. Geol. Surv. India, Vol. XXXVI, Part 4, 1908; 31 pp.) Describes the occurrence, composition of jadeite and the geology of the district in which it is found. Illustrated.

RARE METALS

8286—TANTALUM—The Rare Metals, IV.—Tantalum. Charles Baskerville. (Eng. and Min. Journ., Dec. 5, 1908.) Describes the composition and occurrence of tantalite, yttratanatite, loranskite, samarskite and microlite. 20c.

8287—THORIUM—The Rare Metals, V.—Thorium. Charles Baskerville. (Eng. and Min. Journ., Dec. 26, 1908; 1 1/2 pp.) Gives a list of thorium minerals, dis-

cusses the use of thorium and describes the minerals thorite, orangite, uranochlorite, aegirine, monazite and thorianite. 20c.

8288—VANADIUM AND ITS ESTIMATION. George Auchy. (Iron Age, Nov. 12 and Dec. 3, 1908; 4 pp.) Discusses the advantages and disadvantages of vanadium in so far as these are at present known. Gives methods for the estimation of vanadium. J. Kent Smith replies to the paper and gives his views on the question. 20c.

8289—VANADIUM—The Commercial Use of Vanadium. T. F. V. Curran. (Iron. Min. Rev., Nov. 13, 1908; 1½ pp.) Describes the use of vanadium in connection with steel used for locomotive frames, steel springs and the effect of vanadium on cast iron and copper. 20c.

TIN

8290—BOLIVIA—Tin Mining in Bolivia. (Am. Min. Rev., Nov. 7, 1908; 1 p.) Abstract of paper read by John Pemberton before the Royal Cornwall Polytechnic Society of England. Briefly describes the mines and conditions existing in Bolivia. Illustrated. 20c.

8291—DRESSING—Notes on Tin Dressing. W. H. Hutchins. (Instn. Min. and Met., Bull. Nos. 50 and 51, Nov. 12 and Dec. 10, 1908; 37 pp.) Describes the dressing operations at South Crofty mine, Cornwall, and includes a series of tests, the object of which was to determine the losses in connection with tin dressing and their nature. Illustrated. The paper is discussed by various members, and the author's reply is given. 20c.

8292—TRANSVAAL—The Cassiterite Deposits of the Waterberg. (So. African Min. Journ., Nov. 21, 1908; 1½ pp.) Abstract of a paper by H. Kynaston in the report of the Transvaal Geological Survey of 1907. Describes the Zwaaplaats deposits, the Greenfontein and Roo-depoort occurrences and the pipes and chutes. To be continued. 40c.

TUNGSTEN

8293—IDAHO—Tungsten Ore Deposits of the Coeur d'Alene. Herbert S. Auerbach. (Eng. and Min. Journ., Dec. 12, 1908; 2½ pp.) Scheelite occurs associated with gold, silver, lead, iron and copper. Ore carries 25 per cent. tungsten trioxide. Deposits undeveloped. Illustrated. 20c.

8294—INDIA—Note on an Occurrence of Wolfram in the Nagpur District, Central Provinces. L. Leigh Fermor. (Rec. Geol. Surv. India, Vol. XXXVI, Part 1, 1908; 1 p.) Discusses the geology and mode of occurrence, characteristics of the mineral, origin of the deposits and composition of the ore. 20c.

ECONOMIC GEOLOGY—GENERAL

8295—ANDESITES—Notes on Andesites. Gordon Surr. (Am. Min. Rev., Dec. 5, 1908; ¾ p.) Describes the character and distribution of this volcanic rock and its association with ores. 20c.

8296—ARIZONA—Geologic Reconnaissance of a Part of Arizona. W. T. Lee. With Notes on the Igneous Rocks of Western Arizona by Albert Johannsen. (Bull. No. 352, U. S. Geol. Surv., 96 pp.) The original purpose of this investigation was to determine the water resources of the region and the extent to which they might be developed. Discusses the geology and geography of the district. Illustrated by maps and half tones. 20c.

8297—CALIFORNIA—Notes on Some California Minerals. A. S. Eakle. (Univ. of Cal., Nov., 1908; 9 pp., 2 plates.) Describes the crystallography and characteristics of linarite, caledonite, brochantite, and anglesite from the Cerro Gordo district, Inyo county; celestine from San Bernardino county; stibnite from Hollister, San Benito county; enargite from Alpine county and arcantite from Orange county. 20c.

8298—COPPER-NICKEL WORKS—Die Kupfer- und Nickelwerke und das Nickelvorkommen im Ehemaligen Gebiete der Hohenzollern am Frankwald. Albert Schmidt. (Preus. Zeit. f. B. u. H., Band 56, Heft 4, 1908; 10½ pp.) A historical survey into the copper and nickel mining and smelting industries of Bavaria during past centuries. 20c.

8299—FOSSILS—Notes on a Collection of Fossil Mammals from Virgin Valley, Nevada. J. W. Gidley. (Univ. of Cal., Dec., 1908; 7½ pp.) Describes a collection of specimens indicating species of a middle or lower Miocene age. Illustrated. 20c.

8300—INDIA—General Report of the Geological Survey of India for the year 1907. T. H. Holland. (Rec. Geol. India, Vol. XXXVII, Part 1, 1908; 56 pp.) Describes the work of the India Geological Survey, including its publications, library, museum and laboratory and its work in mineralogy, petrology, palaeontology, etc. 20c.

8301—JAMAICA—Mineral Deposits of Jamaica in West Indies. F. C. Nicholas. (Min. Wld., Dec. 12, 1908; 1½ pp.) Describes the geology of the island and gives theories of the origin of the mineral deposits. Ocher and clay are the most abundant minerals. Illustrated. 20c.

8302—MEXICO—Three Contact Minerals from Velardeña, Durango, Mexico. (Am. Min. Rev., Nov. 13, 1908; 1 p.) Describes the physical and chemical properties, occurrence and other features of gehlenite, spurrite, and hillebrandite. Illustrated. 60c.

8303—NEW MEXICO—Epitome of the Geology of New Mexico. F. C. Jones. (N. M. Bureau of Immigration, 1908; 47 pp.) Describes the occurrence of minerals and metals in New Mexico together with considerable information concerning them. 20c.

8304—OKLAHOMA—Preliminary Report on the Mineral Resources of Oklahoma. C. N. Gould, L. L. Hutchison and Gaylord Nelson. (Bull. No. 1, Okla. Geol. Surv., Nov., 1908; 80 pp.) Describes the occurrence of coal, oil and gas, asphalt, lead and zinc, iron, gold and silver, copper and various rocks and minerals. Illustrated. 20c.

8305—UNDERGROUND WATERS, Meteoric and Magmatic. H. W. Turner. (Min. and Sci. Press, Dec. 12, 1908; 3½ pp.) A discussion of T. A. Rickard's paper on this subject in which further information is given. 20c.

8306—WEST AUSTRALIA—Geology Applied to Mining. Percy Hould. (Aust. Min. and Sci. Press, Dec. 12, 1908; 3½ pp.) Describes the geologic excursion to the Coolgardie district, W. A. Illustrated. 40c.

MINING—GENERAL

8307—ACCIDENT—The Late Mount Morgan Accident. (Queensland Gov. Min. Journ., Oct. 15, 1908; 1¼ pp.) Report of the mine inspector on the accident which occurred at the Mount Morgan mine, in which sixteen men were killed due, it was found, to an unexpected fall of rock. Illustrated. 60c.

8308—ACCIDENTS—Prevention of Mine Accidents. (Eng. and Min. Journ., Dec. 5, 1908; 7¼ pp.) Gives a summary of the laws relating to the prevention of mine accidents. Only four States have passed comprehensive laws regulating metalliferous mining and several States have no laws. 20c.

8309—ACCIDENTS BY ELECTRICITY. (Ber. d. Ver. d. Bergbauingenieure im Jahre 1907. (Preus. Zeit. f. B. u. H., S. Band 56, Heft 4, 1908; 17 pp.) Describes and explains, with numerous illustrations, the causes of the accidents in Prussia during 1907 due to electricity in mining plants. 20c.

8310—ACETYLENE as an Underground Light. William F. Slaughter. (Proc. Lake Superior Min. Inst., June, 1908; 3 pp.) Discusses the uses of acetylene underground and compares the cost of candles and calcium carbide. Illustrated. 20c.

8311—ACETYLENE ILLUMINATION—Alumbrado de Minas por Medio de Acetileno. (Revista Minera, Oct. 24, 1908; 3½ pp.) Opinions of various European engineers on illumination of coal and other mines by acetylene lamps. 40c.

8312—ASSESSMENT WORK ON MINING CLAIMS. W. E. Colby. (Min. and Sci. Press, Dec. 12, 1908; 1½ pp.) Briefly describes the requirements of locating mining claims and the amount of work which must be done upon them. 20c.

8313—BLASTING—The Theory of Blasting with High Explosives. E. M. Weston. (Journ. Chem., Met., and Min. Eng., No. 8, Africa, Oct., 1908; 7½ pp.)

Discusses breaking ground by the use of high explosives, including some of the theoretical side of the problem. Illustrated. 60c.

8314—BROKEN HILL—Mine Methods and Timbering. W. H. Storms. (Am. Min. Rev., Nov. 21 and 28, 1908; 1½ pp.) Describes underground, open cut and sloping-stope systems used at Broken Hill, N. S. W. Illustrated. 40c.

8315—CANADA—A Visit to the Mineral Districts of Canada. William Precheville and H. F. Marriott. (Inst. of Min. and Metallurgy, Dec. 10, 1908; 22 pp.) Describes the mineral resources of the Canadian mining districts which were visited by members of the Canadian Mining Institute. 20c.

8316—CAVING SYSTEM—Mine Methods and Timbering. W. H. Storms. (Am. Min. Rev., Nov. 7, 1908; 1 p.) The present instalment deals with the caving system of mining as practiced at the Pewabic mine, Iron Mountain, Mich. 20c.

8317—CHANGE HOUSE—Benefits of a Modern Change House for Miners. C. J. Stone. (Min. Wld., Dec. 12, 1908; 1¼ pp.) Discusses the advantages of a well arranged, comfortable change house and describes typical buildings of this character at Butte and in the Lake Superior copper country. Illustrated. 20c.

8318—COLORADO—La Plata Mountains, Colorado. R. I. Tull. (Min. and Sci. Press, Nov. 28, 1908; 3¼ pp.) Describes the rejuvenation of this camp, which began its existence in 1873 and has lain dormant ever since except on a few occasions when it attracted attention for a short time. Illustrated. 20c.

8319—COMPRESSED AIR—Controlling the Output of the Air Compressor. Frank Richards. (Eng. News, Nov. 5, 1908; 1 2/3 pp.) Discusses losses which occur in air compressors and the proper method of handling in order to get maximum efficiency. Illustrated. 20c.

8320—COMPRESSED AIR—Explosion in Compressed Air Main. J. A. Burgess. (Min. and Sci. Press, Nov. 28, 1908; 1¼ pp.) Gives facts concerning the explosion in the compressed air main of the Tonopah Mining Company caused by the presence in the system of an inflammable gas or, possibly, fine carbonaceous dust; also mentions some precautions to be taken to prevent such an accident. 20c.

8321—COMPRESSED AIR for Mining in Cobalt District. Alex. Gray. (Min. Wld., Dec. 12, 1908; 2¼ pp.) Discusses factors influencing the supply of compressed air in the Cobalt district, Ontario. There has been a marked increase in steam and gas producer plants in the last four years. Gives the cost of compressing air. Illustrated. 20c.

8322—COMPRESSED AIR—The Hygiene of Work in Compressed Air. (Eng. and Min. Rev., Oct. 24, 1908; 2½ pp.) Discusses some of the physical troubles and diseases brought on by working in compressed air. 20c.

8323—CONSERVATION OF NATIONAL RESOURCES. (Eng. and Min. Journ., Dec. 12, 1908; 1 p.) Discusses the proceedings of the National Conservation Commission in Washington which began its meeting December 1. Deals with the conservation of iron, water and forest resources and the public lands of the United States. 20c.

8324—CONVEYING MATERIAL—Handling Crushed Rock on San Francisco Bay. F. K. Blue. (Eng. and Min. Journ., Dec. 12, 1908; 2½ pp.) Belts and bucket elevators convey the material to and from the bins and load and discharge the hopper barge. Illustrated. 20c.

8325—EARTH EXCAVATION—Die Eisenkettenträger. R. Richter. (Zeit. des Vereines Deutscher Ingenieure, Oct. 24 and 31, 1908; 11 pp.) An exhaustive description, with numerous shop drawings, of various types of dredges for excavating in earth. 20c.

8326—EDUCATION—The Relation of American Mining Schools to the Mineral Industry. L. E. Young. (Min. and Met. Journ., Nov. 5, 1908; 3 pp.) Discusses mining engineering courses and methods in which they equip the engineer to meet mining problems as he finds them in the field. 20c.

8327—EXPLOSIONS—Mittellungen über Einde der Bemerkenswerten Explosionen beim Preussischen Steinkohlenbergbau im Jahre 1907. (Preus. Zeit.

METALLURGY-GENERAL

822—H. H. U. S. Band 56, Heft 4, 1908; 13 pp.) Describes, with diagrams, the causes of some disastrous mine explosions in Prussia, during 1907.

823—FIRE—Extinguishing the Fire in the Testasecca Mine, Sicily. F. C. Chrambach. (Inst. Min. and Met., Nov. 12, 1908; 4 pp.) Describes the method of extinguishing the fire in this Sicilian sulphur mine in which rescue apparatus was employed instead of following the usual method of hermetically sealing the mine workings. Illustrated.

824—INDIA—Sketch of the Mineral Resources of India. T. H. Holland. (Geol. Surv. of Ind., 1908, 97 pp.) Describes the geology, general nature of the mineral industries, the chief mineral products, conditions for the grant of mineral concessions and gives a list of the literature on the subject. Illustrated by maps. 60c.

825—INDIA—The Mineral Production of India During 1907. T. H. Holland. (Rec. Geol. Surv. India, Vol. XXXVII, Part I, 1908; 71 pp.) Gives statistics of the production of chromite, coal, diamonds, gold, graphite, iron ore, jadeite, magnesite, manganese ore, mica, petroleum, gems and the more common minerals. The statistics cover a period of five years.

826—MEXICO—Description of Part of the Alarcón District in the State of Guerrero, M. H. Carpenter. (Mex. Min. Journ., Dec., 1908; 1½ pp.) Briefly describes the occurrence of ore and some of the mines in the district.

827—MEXICO—Location and Survey of Mining Claims in Mexico. F. H. Hider. (Mex. Min. Journ., Dec., 1908; 1½ pp.) Gives the requirements which are necessary to locate mining claims in Mexico. 20c.

828—MEXICO—Mine Labor and Supplies in Mexico. Mark K. Lamb. (Eng. and Min. Journ., Dec. 26, 1908; 3 pp.) Discusses the quality and cheapness of native labor, cost of machinery, trade in mining supplies and sources from which materials are drawn. Illustrated. 20c.

829—MEXICO—On the Trail Through Western Chihuahua. Charles McC. Anderson. (Mex. Min. Journ., Dec., 1908; 1½ pp.) Describes the author's experience in Chihuahua and tells of lost mines and hidden treasure which are believed to be in this State. Illustrated. 20c.

830—MINE ATMOSPHERE—Der Einfluss der Luftdruckschwankungen auf den Wasserandrang und den Gasaustritt in Bergwerken. Chr. Mezger. (Glückauf, Oct. 24 and Oct. 31, 1908; 1 p.) Discussion, with experimental results, of the moisture and gas contents of mine atmosphere under varying conditions of temperature, season, etc. 60c.

831—MINERS' CLUB—The Cactus Club at the Copper House Mines, Utah. Hanchett. (Eng. and Min. Journ., Dec. 19, 1908; 1½ pp.) Describes a co-operative organization controlled by the mine employees which has proved successful both socially and financially. Illustrated. 20c.

832—MINING LAW—Railroad Grants on Mineral Lands. Thomas E. Kepner. (Eng. and Min. Journ., Dec. 5, 1908; 1 p.) Quotes a number of decisions handed down by various courts relating to the subject. 20c.

833—PRUSSIA—Die Bergwerksindustrie und Bergverwaltung Preussens im Jahre 1907. (Preuss. Zeit. f. B. u. S., Band 56, Heft 4, 1908; 40 pp.) A review of the mineral and metal mining industries of Prussia during 1907.

834—SHAFT DRAINAGE—Ueber eine Methode zur Ermittlung der zu Wältigen Wasserzuflüsse beim Uebergang vom Schachttaufen in Tonne Wasser zur Abteufarbeit auf der Sohle. Dr. Müller. (Glückauf, Oct. 24, 1908; 3 pp.) Develops a number of formulas of interest to those engaged in sinking shafts through water-bearing rocks. 40c.

835—SHAFT SINKING—Sinking a Reinforced Concrete Shaft. L. L. Brown. (Eng. News, Sept. 24, 1908; 3 pp.) Describes the method of sinking a shaft for the Woodward colliery of the Delaware, Lackawanna and Western R. R. Co. in the first 80 feet of which a reinforced concrete caisson was used to penetrate the extremely wet and porous overlying strata. 20c.

836—SHAFT SINKING—The Cannock and Huntington Sinkings. C. H. Bailey.

(Journ. Brit. Fed. Soc. Min. Students, Oct., 1908; 6½ pp.) Briefly describes the chief points in the Kind-Chadron system of sinking and more carefully describes the point which was remarkable about the Cannock and Huntington sinkings, namely, the fact that at the last moment in both pits a weak point was apparent in the tubing which led to the ultimate abandonment of the shafts. Illustrated.

837—SIGNALING—Electric Signaling at Mines. (Eng. and Min. Journ., Dec. 12, 1908; 3 p.) Gives methods of electric signaling in use at the Great Boulder Proprietary mines, Kalgoolie, W. A. Illustrated. 20c.

838—SOUTH CAROLINA—The Mines of South Carolina. H. L. Scaife. (Eng. and Min. Journ., Dec. 19, 1908; 1½ pp.) Describes the occurrence of minerals in South Carolina, which is more noted for the diversity of its minerals than for the magnitude of its production. 20c.

839—SUPPLIES—Economy in Purchasing Supplies. Robert Job. (Journ. Franklin Inst., Nov., 1908; 5 pp.) Discusses the importance of an accurate study of the purchase of supplies and recommends systematizing in order to buy nothing unnecessary or of a quality better than actually needed. 60c.

840—TIMBER—Preservation of Timber. F. H. Mason. (Min. and Sci. Press, Dec. 19, 1908; 1½ pp.) Describes the treating of timbers with various preservatives and describes the method used and the tests made. Illustrated. 20c.

841—TIMBERING—Mine Methods and Timbering. W. H. Storms. (Am. Min. Rev., Oct. 24, 1908; 1½ pp.) Continuation of article previously indexed. Describes the California modifications of the square-set system of timbering, including the cap-sill. Illustrated. 20c.

842—TIMBERING—Mine Methods and Timbering. W. H. Storms. (Am. Min. Rev., Dec. 5, 1908; 1 p.) Describes the block system in the Central mine and the flying box method of extraction. Illustrated. 20c.

843—VENTILATION—The Ventilation of Mines. A. V. and V. J. Sarvas. (Aust. Min. Stand., Oct. 7, 14 and 21, 1908; 5 pp.) Continuation of article previously indexed, dealing with distribution of air in workings, use of compressed air for ventilation, splitting air currents, etc. 31.

ORE DRESSING-GENERAL

844—CONCENTRATION—The Simpler Methods of Concentration. Leggett. (Palmer. (Salt Lake Min. Rev., Oct. 30, 1908; 2 pp.) Describes some of the concentrating devices which have been successful and which are simple in construction. Illustrated. 20c.

845—ELMORE PROCESS AT BROKEN HILL—Die Finanzielle Seite des Elmore-Verfahrens für die Broken-Hill Tailings. C. Güpner. (Metallurgie, Oct. 22, 1908; 2½ pp.) Data as to the financial saving accomplished by the Elmore process working on tailings from Broken Hill. 40c.

846—GERMAN PRACTICE—Ueber moderne Aufbereitung von Kohle und Erz. E. Rudand-Klein. (Oest. Zeit. f. B. u. H. Aug. 1, 1908; 4 pp.) Continued description of article previously indexed. 40c.

847—JIGGING—The Separation of Metallic Ores by Jigging. Arthur Taylor. (Instn. Min. and Met., Nov. 12, 1908; 12 pp.) A discussion by members, in which additional information is supplied. Illustrated.

848—SAMPLING BY MACHINES. T. R. Woodbridge. (Eng. and Min. Journ., Dec. 5, 1908; 3 p.) A discussion of the article by John A. Church giving additional information on the subject. 20c.

849—SLIME TREATMENT—The James Slimer. M. T. Hoster. (Eng. and Min. Journ., Dec. 12, 1908; 1 p.) Illustrated description of the James concentrating table, together with method of operation. 20c.

850—TESTING PLANT—The Hennig Testing Plant and Metallurgical Laboratory. (Eng. and Min. Journ., Dec. 5, 1908; 1½ pp.) Describes this laboratory and testing plant which is well equipped for scientific research; also the Hennig ore concentrator which has several new and important features. Illustrated. 20c.

851—BY-PRODUCT GAS—Die Bewertung der Hooiboden- und Koksfasen in Rentabilitätsrechnungen. K. Rummel. (Stahl u. Eisen, Oct. 21, 1908; 2½ pp.) A discussion of the commercial value of the gases given off by blast furnaces and coke ovens. 40c.

852—CAPACITY OF VATS—The Capacity of the Vat for the Foot of the Vat. W. A. Caldecott. (Journ. Chem. Met. and Min. Soc. of So. Africa, Oct., 1908; 1 p.) A useful table showing the capacity of vats containing dry sand, slime-pulp and dry slime per foot depth of pulp. 60c.

853—CONVEYING MATERIALS—The Elements of Chemical Engineering—II. Chem. Engr., Nov. 1908; 12 pp.) Continuation of article previously indexed. Describes methods of conveying liquids. Illustrated. 40c.

854—IRON-PHOSPHORUS ALLOYS—Experimentelle Thermische und Metallgraphische Untersuchung über das System Eisen-Phosphor. E. Gercke. (Metallurgie, Oct. 22, 1908; 3½ pp.) Results of experiments on the thermal properties and microscopic structure of alloys of iron and phosphorus. 40c.

855—ORE TREATMENT—Newer Ore Treatment and Metallurgical Processes and the Metallurgical Processes at the Elmore. C. Christensen. (Eng. Mag., Dec., 1908; 21 pp.) Gives the latest practice in modern cyanide processes, the lixiviation of oxides and carbonates of copper, the electrolytic treatment of copper sulphide ores, the Elmore vacuum process and the electrically operated copper converter. Illustrated. 40c.

856—SLAG ANALYSIS. Charles S. Palmer. (Min. Sci. Dec. 24, 1908; 1 p.) Discusses the peculiar condition in the analysis of blast furnace slag which influences its solution by hydrochloric acid. 20c.

857—SMELTER COST-KEEPING. O. E. Jaeger. (Ballarat Sch. Mines Students' Mag., Nov. 3, 1908; 3 pp.) Discusses certain methods of keeping cost sheets at smelting works. 40c.

858—SMELTER SMOKE. (Min. and Sci. Press, Dec. 19, 1908; 1½ pp.) This subject is discussed editorially and conditions existing at several smelting centers are described. 20c.

MINING AND METALLURGICAL MACHINERY

859—BELT CONVEYERS—The Use and Performance of Belt Conveyors. W. Boecklin. (Eng. Mag., Dec., 1908; 17 pp.) Discusses in a thoroughly practical manner the questions of mechanical construction, of care and upkeep and of economy in operation of belt conveyors. Illustrated. 40c.

860—CANADIAN MINING PLANTS—Notes on Plant in Mining Districts of Canada. R. E. Commey. (Inst. Min. and Metallurgy, Dec. 10, 1908; 15 pp.) Gives a brief description of the plants at the mines visited during the excursion of the Canadian Mining Institute. The descriptions are brief and no claim of being complete or detailed.

861—CRUCIBLES—Prolonging the Life of a Crucible. D. L. Johnson. (Metal Ind., Nov., 1908; 2½ pp.) Describes some of the conditions which reduce a life of a crucible and suggests systematic treatment to overcome this condition. 20c.

ANALYTICAL CHEMISTRY

862—POTASSIUM PERMANGANATE SOLUTION—The Standardization of Potassium Permanganate Solution and Its Subsequent Use in Titrating Iron. C. Differhaus and E. H. Fischer. (Sch. Mines Quart., Nov., 1908; 4 pp.) The authors found that the only suitable and unassailable standard for acidity existing at the present time is sodium oxalate, proposed by Sørensen. 60c.

INDUSTRIAL CHEMISTRY

863—ATMOSPHERIC NITROGEN—The Fixation of Nitrogen. F. R. Carpenter. (Journ. Ind. and Eng. Chemistry, Jan., 1909; 1 p.) Gives a brief description of the process of Frank & Caro for the manufacture of calcium cyanamides. 60c.

The Engineering and Mining Journal

NEW YORK, JANUARY 16, 1909.

NO. 3.

Rio Plata Mine and Mill, Western Chihuahua

The Vein Is Developed by Adit Levels from the Side of a Cañon,
and the Ore Is Treated by Sliming and Cyanide Agitation

B Y H. J. B A R O N *

The property of the Rio Plata Mining Company is situated in the Sierra Madre mountains, in the southwestern corner of the state of Chihuahua, about 20 miles from the Sonora and Sinaloa state lines. It is within the Arteaga mining district,

Mexico & Orient Railway, about 85 miles in a southwesterly direction. For the latter distance there is a good mountain trail. In its progress westward the railroad will pass within 20 miles of the company's Santa Bárbara mine, and this will

elevation at the Santa Bárbara mine is 3100 ft. The location is within the rich and proved mineral belt extending north-south about 225 miles and east-west 100 miles, on the western drainage of the Sierra Madre range, and within whose

RIO PLATA MINE, TAILINGS PONDS IN FOREGROUND

municipality of Chínipas, and 6 miles from the old silver camp of Guazapares. It is distant from Chihuahua approximately 285 miles, and from Sánchez, the present terminus of the Kansas City,

minimize one of the difficulties attending the equipment and operation of the property.

The region is extremely rugged, towering mountains and precipitous cañons being features of the 85-mile trail to the camp, as well as of the camp itself. The

boundaries are included many of the state's most productive mines. Beginning with the Guadalupe y Calvo section on the south and terminating at the Dolores mine at the north, are the Morelos, Batopilas, Urique, Barranca de Cobre, Palmaréjo, Uruachic, Jesús María, Pinos

*Manager, Mexican Chemical Company, S. A. Chihuahua, Mexico.

Altos, Concheño, Dios te Guie, Bufo, Trinidad, República, Mulatos and others of past and present production records. The accompanying map gives the location of most of these mines as well as a good idea of the region's transportation facilities. The present railroad station for camp Rio Plata, Sánchez, is not shown, but it is to the south of Bocoyna at the point designated as "8152 ft., highest point on the Orient Railway."

THE MINE

The company's holdings comprise mineral rights to 187 acres and surface rights to 2700 acres of timber and ranch land,

presents many interesting features. The mine is *not* an *antigua* with a past record, but is only four years old, now entering upon its earning career. It was formerly owned by Mexican ranchers, who made but one shipment, consisting of 22 tons of ore of a net value of 38,000 pesos. It was acquired by the present company a little more than two years ago, and on terms that almost resulted in its reverting to the original owners. The bond for its purchase required that the mill be placed in operation within six months from the date thereof, under penalty of forfeiture, and notwithstanding serious delays in machinery shipments, the mill was placed in

from the horizontal. Its uniform width is remarkable, the average of that exposed by nature, as well as by the 2500 ft. of workings, being between 4 ft. and 6 ft. In some places, as at the rich outcrop first worked by the Mexicans where faulting is noticeable, its width is as great as 12 ft., while the surrounding country rock to a like distance carries workable material. The richer ore runs in shoots, usually on the hanging-wall side and separated by variable areas of lower-grade ore. These rich shoots vary in width from 1 in. to 12 in. and in value from 200 oz. to 4000 oz. silver to the ton.

The gangue is mainly bluish-colored

MAP OF SOUTHWESTERN CHIHUAHUA, SHOWING SITUATION OF RIO DE PLATA

all in one tract, together with water rights on the Septentrion river, a stream traversing the property for a distance of 6000 ft., and furnishing excellent power facilities. The mesas within the ranch tract are heavily timbered with pine and oak, the former of long-leaf variety, many of the trees being 3 ft. in diameter. The location of the mineral claims, on both sides of the river and within the ranch tract, is such as to cover every possible dip of the veins. It covers the vein for a distance of 2000 feet.

Historically and geologically, as well as topographically, the Santa Bárbara mine

operation on the last day of the prescribed period. At that time the nearest railroad point was 125 miles away, and the trail to the camp was a most difficult one.

The original discovery of the mine was made easy by the eroding cañon, Santa Bárbara by name and through which runs the Septentrion river, which cuts the vein at right angles, exposing it for a depth of nearly 1800 ft., from the top of the mountain to the river bottom.

NATURE OF THE DEPOSIT

The vein is a fissure in diorite, with a course south 25 east and a dip of 17 deg

quartz, an approximate analysis being as follows: silica, 80 per cent.; iron, 0.75; calcite, 2; sulphur, 32; manganese, 0.13; alumina, 5 and magnesium, 2 per cent. The ore carries chiefly silver, which occurs as the sulphide, bromide and native, the predominating occurrences being in the order given.

DEVELOPMENT

At the time of the transfer of the property, the development amounted to about 1100 ft. of tunnels and open cuts, while the total of laterals and verticals today is

more than 2500 ft. in addition to which there are several hundred square feet of stoped areas. The mine is so situated that it is readily exploited by means of short tunnels. The deep cañon has proved superior to a shaft of like depth in exposing the vein for more than 1800 ft., while the precipitous rise of the mountain, in a series of benches, makes economical the driving of adits at depth.

The extent and nature of the development is shown in the accompanying map. The six openings, the five upper of which are connected by winzes and upraises, are

they stripped the vein for 60 ft., to an average depth of 25 ft., in the progress of which the 22 tons of high-grade sulphide ore was mined and shipped. The walls of this pit have since been broken into; samples give assays as high as 1600 oz. per ton.

The workings, all of which are in ore, have demonstrated a remarkable continuity and permanency of the vein, as well as the comparative absence of serious faulting. In driving the lower tunnel some apprehension was first felt concerning the apparent faulting, but this has vanished

METHOD OF MINING

The vein as stoped between the San Miguel and San Gonzalo tunnels was 5 ft. in width on the average and in places as great as 12 ft. There has been mined between these levels in an area of 150 sq. ft., about 10,000 tons of 110-oz. ore. The breasts of the several adits as well as the faces of the raises and the bottoms of the winzes are all in ore and there are in reserve large bodies in all of the stopes. Engineers' reports place the value of the ore available from present developments at \$2,000,000.

The ore for the entire width of the vein is mined by the overhead stoping method, the vein being well opened up into fairly even blocks by the several levels and winzes. All of the ore is dropped for extraction to the San Antonio or No. 2 tunnel, from which it is trammed in mule cars to the surface. Connections are now in progress between tunnels Nos. 2 (San Antonio) and the Obra by way of the winze from the former, and a 15-hp. Girard hoist is installed in the tramway or San Antonio level for the hoisting all ore mined below that level.

The vein walls are throughout remarkably firm, regular and smooth, causing the ore to break away readily. No timbering other than an occasional stull is required. Nor is any provision for caring for water necessary; the workings are perfectly dry, with the exception of the lowest tunnel where the flow is about 2 gal. per minute. That the mine will continue dry seems assured, inasmuch as La Obra tunnel is at least 40 ft. above the highest known water mark of the river. The various connections between levels have up to date provided natural ventilation, which will probably be adequate for an indefinite period, under the blocking-out system of mining followed.

In ground-breaking hand drills only are used at present, but on the completion of the power plant electrically driven air drills will be substituted. The only sorting resorted to is the separation of the ore in the high-grade shoots, this separation being done in part in the breaking and in part by hand selection underground and at the surface. The amount of this high-grade ore of an average value of 1800 oz. silver secured is from 5 to 15 tons monthly. The daily tonnage of the mine now is about 60 tons, while the development work of the month totals about 200 feet.

THE MILLING PLANT

From the main working tunnel to the mill, a distance of 1400 ft., the ore is transported in cars of 1000 lb. capacity, drawn by mules, one mule pulling a train of six cars. Electric haulage, both underground and on the surface, will later be used. One of the accompanying photographs shows the present concentrating mill and the cyanide plant now in process

FLOW SHEET, CONCENTRATING MILL AND CYANIDE PLANT

as follows: La Obra, 275 ft. in length, driven at a point 60 ft. above the river; San Antonio, or tramway level, 400 ft. long, 200 ft. above La Obra; San Miguel, 350 ft. long, 75 ft. above San Antonio; San Felix, 250 ft. long, 75 ft. above San Miguel; San Gonzalo, 180 ft. long, 85 ft. above San Felix, and San José, 300 ft. long and 100 ft. above San Gonzalo. The San José tunnel is vertically 1100 ft. from the apex of the vein on the mountain top. The San Felix is the original opening and is driven at a point where the Mexicans were able to make a "patio" and where

since the opening up of a 6-ft. orebody in the bottom of a 60-ft. winze sunk from the tramway level above.

Throughout the workings the vein shows an average width of more than 4 ft. and gives evidence of widening as the lower levels are continued. The high-grade shoots of bornides and native silver have been encountered on all levels. The average value of the ore exposed in the various tunnels, winzes and raises is estimated to be 100 oz. silver per ton, while that of the ore hitherto mined is 110 oz. per ton.

of construction. Another shows the accumulated tailings and reservoir.

The cyanide plant will employ the all-sliming process, but on lines somewhat different from those ordinarily followed in the cyanidation of Mexican silver ores. The method was worked out by the company. The tests on a working scale have been very encouraging. The cyanide annex is expected to be in operation early in 1909.

The concentrating mill is a frame structure, built on the slope of the mountain-side, so as to permit of gravity flow of material throughout. It has an equipment of 25 stamps and the necessary concentrators, pans, settlers, etc., to afford a daily capacity of 60 tons, while the cyanide plant is being built for handling 100 tons of accumulated and current tailings.

The ore is dropped from the cars into ore bins of 200-ton capacity, through 8x10 ft. grizzlies of about 1½-in. openings, the oversize from the grizzlies going to two

five in number, while the overflow, together with the table slimes, is launder-delivered to two Wilsley slimers and one Frue vanner. Concentrates are made over both the Card tables and sliming machines and the tailings from the former are sent by launder to eight Wheeler grinding pans of 5 ft. diameter for re-grinding to about 150 mesh, from which the material is delivered by gravity launder to two Traylor settling tanks, of capacity and type as the one earlier noted. The overflow from the settling tanks goes to a 10x10x16-ft. Dimmick classifier; the clarified water from the classifier is returned by 2½-in. pump through a 2½-in. iron pipe, 162 ft. long, to the mill-supply tanks of 10x15 ft. dimensions, placed outside and at the head of the battery room.

From the settling tanks the pulp is delivered through a 4-in. iron pipe to four Pachuca agitating tanks 15 ft. in diameter and 45 ft. deep. These tanks, as is the case with all of the others in and about

25-h.p. variable speed drives the compressor for air agitation in the tanks; the eight Wheeler regrinding pans are driven by four 25-h.p. constant-speed motors, one motor to every two pans; one of 10-h.p. operates the 2½-in. pump which returns the water to the mill-supply tanks; one 20-h.p. motor runs the Moore vacuum filter while the 4-in. sand pump is operated by a 20-h.p. motor and the 7x10-in. vacuum pump is driven by a 15-h.p. motor, while one of 2½-h.p. operates the precipitate filter press. For a reserve pump set in the furnace room a 25-h.p. variable-speed motor is installed.

The milling machinery was furnished by the John A. Traylor Machinery Company, of Denver, and the Compañía Industrial Mexicana, of Chihuahua. The steel tanks were built by the El Paso Foundry and Machinery Company, of El Paso.

Concentration is at the ratio of 30 to 1, and very rich concentrates, containing

RIO PLATA MILL

NATURAL DIVERTING WALL, INTAKE DAM

rock breakers, of jaw type and Wheeler pattern, set to crush to less than 1¼ in. Plunger feeders facilitate delivery to the batteries, which include five stands of five stamps each. The stamps weigh 1000 lb. and drop 6 in. at the rate of 108 drops per minute. The cam shaft is 6 in. in diameter. The battery screens of 24 mesh are of the Tyler woven-wire type. The mortars are of the sectionalized type made by the Compañía Industrial Mexicana of Chihuahua; they are of straight-back, high-feed pattern with screen space 13 in. wide; they weigh, without the steel housings, about 3000 lb., but for mule-back transportation are built so that the heaviest piece is less than 300 pounds.

METHODS OF TREATMENT

Crushing is performed in 0.1 per cent. cyanide solution. The battery pulp goes to a Traylor settling tank, 12x12x24 ft., of V-shape, from which the heavier material is drawn off at the bottom to Card tables,

the reduction plant, are constructed of 3/16-in. steel. The pulp will be agitated 12 hours in 0.25-per cent. cyanide solution. After agitation, the pulp will be drawn off through a 4-in. pipe to the Moore vacuum filter press having 28 leaves, 6x10 ft., affording 100 tons capacity. The solution from the press is to be pumped to two 15x15-ft. sand-filter tanks, from which it will be drawn off to six 10-compartment zinc boxes. In precipitation, fine zinc shavings will be used, and the precipitates are to be filter-pressed before going to the retorting furnace in the melting room adjoining.

MOTORS AND EQUIPMENT

The milling plant is driven by General Electric motors throughout. One 25-h.p. motor, of 600 r.p.m. constant speed, operates the crushers and two of like power and speed drive the stamps; one 10-h.p. motor, of variable speed, operates the concentrators and slimers and another of

about 50 per cent. of the value of the ore, are turned out, the mixed concentrate products from the tables and slimers averaging 1500 oz. silver per ton. The gold contents of the concentrates are only about 1 oz. to every four tons.

In the milling operations thus far carried on there has accumulated approximately 11,000 tons of tailings of an average value of 51 oz. silver. The tests have demonstrated a probable working extraction by cyanidation of 86 per cent. of this silver, by grinding to 150 mesh and treatment in 0.25-per cent. solution, with a cyanide consumption of about 5.6 lb. to the ton of tailings. The total extraction by concentration and cyanidation will, therefore, probably be more than 93 per cent. of the assay values of the ore.

THE POWER PLANT

The abundant water supply from the Septentrion river has been utilized in the generation of electric power. At the mine

the stream has an actual fall of 205 ft. in 5000 ft., and at one place back of the camp there is one waterfall which is about 1200 ft. high during the rainy season. The water, taken from the river at a point 4000 ft. from the mill, is delivered to the storage reservoir in a wooden flume 5300 ft. long. The flume is 20 in. deep and 40 in. wide, and is constructed of 2-in. pine planking.

The in-take dam is at a bend in the stream where a 20-ft. rock face makes a natural diverting wall. For a space of 25 ft. square the uneven river bottom has been rock-floored and cemented to insure better storage. At approximately right angles to the diverting wall there is a 25-ft. face of vertical cliff which has been tunneled for a distance of 150 ft. for carrying the water to the flume system. The natural diverting wall and rock tunnel are shown in an accompanying illustration.

With a flow of 1200 cu. per minute and under a head of 163 ft., the water is delivered to the 6-ft. Pelton wheel, which drives, by means of belt connections, the two 100-kw. General Electric generators, of alternating current, 60-cycle, 480-volt type. This power, 266 h.p., is adequate for present purposes. It will not be difficult at any time, with the abundant water supply, to increase the capacity of the plant, if occasion arises. The present power is utilized in driving the mine and mill machinery. Another Pelton wheel 2 ft. in diameter drives a 25-h.p. General Electric generator which runs the electric-light plant of 150 lights. The cost of power is estimated at 20 pesos per horsepower-year.

OPERATING COSTS

The operating costs at a point so far removed from railroad transportation are necessarily high. Mining costs are given as 3.70 pesos for ore-breaking and sorting, and 24 centavos for tramming, or a total of 3.94 pesos per ton of ore mined. The development costs are 12.34 pesos per foot of ground broken, the Mexican drillers being paid at the rate of 40 centavos per foot drilled. The cost of concentrating is 1.74 pesos per ton of ore treated while the cyanidation costs are estimated at about 4 pesos per ton. Mexican labor is employed, there being but six white men all told at the mine. Peon laborers, of which there is in the region an abundance of more than average efficiency, are paid at the rate of 1.50 pesos per day of 10 hours. The drillers alone work by the piece.

The freighting expenses from Sánchez on the railroad to the camp are as follows: Ordinary freight, 12 pesos per *carga* of 300 lb.; steel tanks, sectionalized, and similar articles, 15 pesos per *carga* of 300 lb. The cost of delivering ore and concentrates to the railroad is 12 pesos per 300 lb., or 80 pesos per ton, while from Sánchez to El Paso, Texas, the railroad freight is 10

pesos per ton, making the total cost of delivery of product to the smelter 90 pesos per ton. Twenty-two days are required for a round trip of the freighters to the railroad.

THE CAMP AND ORGANIZATION

The camp is picturesquely situated in the cañon between the mine and mill. The buildings, numbering five and substantially built of adobe, comprise a large boarding house, store, warehouse, assay office and officers' quarters. There is also a settlement of 400 Mexicans nearby. There are telephone and telegraph connections to the mine. The operating force at the mine numbers about 125. The superintendent in charge is H. W. Edmondson.

The Rio Plata Mining Company is capitalized at \$2,000,000, the largest holders of the stock being a few New York capitalists. The officers of the company are

Mexico's New Mining Law

The new mining law of Mexico consists of 150 articles embodying the present laws and the decrees and regulations that have been in force, with some important changes, mostly with the view of removing conflicting legal provisions. The regulation as to *pertenencias* remains unchanged. Article 3 provides that matters relating to mining property shall be subject to the civil code of the federal district, except when specifically determined otherwise in the law itself.

The provisions relating to the restriction of mining rights to Mexican companies is absent from the draft submitted; and the restrictions which required the foreigner to secure executive permission to locate claims in the border states is made to apply only to an 80-kilometer

SANTA BARBARA MINE, RIO PLATA MINING COMPANY

as follows: President, H. W. Miller; vice-president, A. B. Cordner; and secretary-treasurer, John L. Toppin. These gentlemen and nine others, including D. W. Shanks, of Los Angeles, comprise the directorate. Mr. Shanks is also general manager, with offices at Chihuahua.

A suction gas-producer system is used at the New Chums Goldfield mine, Bendigo, Australia, for running the mill. Formerly the cost of steam power generated by burning wood was, according to Donald Clark, *Aust. Min. Stand.*, Sept. 23, 1908, 1s. 3.5d. per ton of ore crushed. During the short time that the gas-producer system has been running the cost of power has been 3.18d. per ton of ore crushed.

zone on the boundaries. The law will become effective July 1, 1909, except that the provisions as to prospecting permits become effective after the promulgation of the law.

Bismuth

The price for bismuth which was established by the European combination at 6s. 6d. per lb. on July 4, 1907, remained at that price throughout 1908. As in 1907 a small amount of refined bismuth was produced in the United States, but the production is still too insignificant to have any effect upon the price or even to attract the attention of the combination.

Diamond Mine in Pike County, Arkansas

The Gems Are Found in Peridotite Which Is Similar in Every Essential to the Diamond-Bearing Formations of South Africa

BY JOHN T. FULLER*

It is now nearly two years since the first rumors of the discovery of diamonds in their original matrix in Pike county, Arkansas, began to reach the East. This discovery has since been verified by competent engineers and geologists, and active preparations are being made to develop the field on an extensive scale.

It has long been a well known fact that genuine diamonds have been found from time to time on the continent of North America chiefly within the boundaries of the United States. Dr. George F. Kunz is authority for the statement that the first authentic find of a diamond in the United States was in 1832 in the State of Indiana.

the Western Hemisphere, where diamonds have been found in their original matrix.¹

LOCALITY AND HISTORY

The exact location of this Arkansas discovery is Pike county, Sections 21 and 28, Township 8 South, Range 25 West. The diamond-bearing area lies on the east bank of the Little Missouri river near the junction of that stream with Prairie creek. The nearest town is Murfreesboro, the county seat, which is about 2½ miles to the northwest.

Direct rail communication to Murfreesboro will be established in the near future by a branch line which will connect with

the rock resembled closely the diamond-bearing rocks of South Africa, but scouts the idea of its containing diamonds, due to the absence of any bituminous shales surrounding the "pipe," or crater, such as occur about the pipes at Kimberley, and from which it was at that time supposed that the carbon required for the formation of the diamond was derived.

No more notice was taken of this area until 1906 when John M. Huddleston, who had in the meantime purchased the property on which the greater part of the diamond area lies, found the first diamond on Aug. 1, 1906. This was a white stone of 4½ carats. On the afternoon of the

POINT AT WHICH FIRST DIAMOND WAS FOUND

PERIDOTITE OUTCROP ON SOUTH SLOPE

Since that time a number of authenticated finds of diamonds have been made in several States of the Union, among which may be mentioned Virginia, North Carolina, Georgia, California, Idaho, Montana, Indiana, Arizona, Michigan, Wisconsin and Ohio. It is to be noted that in all these cases the discovery was confined to either one, or a few scattered stones, and in no case has the locality where these diamonds originated been discovered.

Attempts have been made to trace the diamonds found in the glacial drifts of Michigan, Wisconsin, and Ohio back to their original source, which is supposed to exist somewhere in Canada, but so far without success. The discovery in Arkansas, therefore, is the first locality, not only in the United States, but also on

the main line of the Kansas City Southern at Ashdown, Arkansas. At present the easiest way to reach the property is by rail from Little Rock to Cooley's Crossing, via Prescott, which is about 6½ miles from Murfreesboro, the latter distance being covered by wagon.

The history of this Arkansas discovery presents several interesting features. First mention of this locality was made as early as 1842, but no report of any accuracy was made until 1800, when the region, including the volcanic area, was mapped and reported on by John C. Branner, who at that time was State geologist.²

In this report Branner mentions that

¹Diamonds have never been found in South America in the true matrix.

²Geological Survey of Arkansas, Annual Report for 1890.

same day a second diamond was found by Mr. Huddleston, who, suspecting that he had found something valuable, although he did not know just what, sent the stones to C. S. Stiff, a jeweler of Little Rock, who pronounced them to be true diamonds.

Mr. Stiff, realizing how important was this discovery, immediately, with several friends who joined him as partners, secured options on the Huddleston tract and on considerable other land adjoining, thus gaining control of by far the greater part of the igneous area. The company thus provisionally formed secured the services of competent geological and engineering advice, and on the strength of the reports made to them, a company, known as the Arkansas Diamond Company, was incorporated for the pur-

*Consulting engineer, Wilkes-Barre, Penn.

pose of mining diamonds on a large scale.

GEOLOGY

The matrix of the diamond is a peridotite which has been described by the late Prof. Henry Carvill Lewis as "a porphyritic volcanic peridotite of basaltic structure," which is named kimberlite.³ This peridotite, or kimberlite, is more popularly known in South Africa as "blue ground."

The use of the term blue ground in connection with this rock is very misleading. Many people are deceived by this term and take it for granted that the diamonds occur in a soft clay soil, or ground which presents no difficulty, or much expense to wash and concentrate. This is not the case. The origin of the term blue ground is interesting. Like most peridotites the greater number of the "diamond-bearing peridotites" show marked changes on exposure to the atmosphere and "weather in place" to considerable depth.

known as a "pipe," which is the neck, vent, or stock, of an old volcano, or dike, filled up solid with the diamond-bearing rock and extending to unknown depth. The Arkansas peridotite has been demonstrated to be in every essential similar to the diamond-bearing peridotites of South Africa, and the most essential characteristic, the actual finding of diamonds within its mass, is fulfilled.

VARIETIES OF PERIDOTITES

I have heard it said, and seen it written, that this Arkansas peridotite shows marked differences from the peridotite of Africa. When it is realized that from the same pipe in Africa a dozen or more different hand specimens of peridotite can be taken, no two of which resemble each other either in inclusions or physical appearance, the folly of attempting to find differences in this Arkansas pipe from hand specimens brought from the African pipes, is evident. The only way they can

The harder varieties of the peridotite, which may and do occur in the same pipe with the softer variety and which are known as "hardibank," are of an entirely different nature. No amount of exposure to the atmosphere will have any practical effect on this rock. In hardness it is equal to the hardest quartzites, and to be concentrated at all, it must first be crushed by powerful crushers. This variety does not weather in place to any extent and forms the hard outcrop which first drew the attention of geologists to the Arkansas pipe.

The concentrate from this diamond-bearing peridotite contains many other minerals besides the diamond, among which may be mentioned mica, hornblende, magnetite, olivine, garnet, etc. In no instance have these minerals, or any other mineral except the diamond, been found in the diamond-bearing peridotite of such quality as to have any commercial value. There is no commercial

FIRST PIT SUNK IN PERIDOTITE

PART OF DIAMOND-BEARING AREA

The fresh peridotite is as a rule of a bluish green color, which changes on weathering to a dull grayish green or yellowish green. During the process of weathering, the rock disintegrates to a great degree and can easily be pulverized between the fingers. It is then, properly speaking, when in this condition, a "ground" and not a rock. This yellow disintegrated peridotite being naturally the top portion of the mass was the rock in which the diamonds were first found and became known as "yellow ground." In time the yellow ground was mined out exposing the hard undecomposed blue peridotite beneath, which was called in contradistinction by the early miners blue ground.

The diamond-bearing peridotites of South Africa occur in what is there locally

be compared is to compare the masses as a whole, and by this method of comparison I can see no radical difference either in formation, occurrence or in the character of this peridotite from those of South Africa.

That the Arkansas peridotite occurs in a pipe similar to its occurrences in South Africa has also been sufficiently demonstrated, by means of bore holes, to be accepted as a fact. The peridotite of the Arkansas pipe, as is also true of the South African pipes, varies considerably in hardness over different parts of the pipe. In most cases the peridotite will disintegrate readily after a few months' exposure to the atmosphere. The softer varieties, which are comparable in hardness when fresh with ordinary sandstones, "weather in place" to depths varying from 20 to 60 ft. and form the famous "yellow ground" of the South African mines.

by-product from the mining of diamonds.

INCLOSING ROCKS

In the nature of the surrounding rock strata the Arkansas pipe differs considerably from those occurring near Kimberley, but it resembles many of the pipes found elsewhere in South Africa. So far as known at present the rock strata surrounding the Arkansas pipe are Carboniferous sandstones, and quartzites, unconformably overlaid by horizontally-bedded Cretaceous sandstones, which are in turn overlaid by a coarse Post-Tertiary conglomerate.

In two places within the peridotite area can be seen the outcrop of a dike of volcanic rock from 5 to 6 ft. wide and of a light blue color. This dike cuts through the peridotite with a strike nearly east and west. It is most probable that this

³Eighteenth Annual Report, De Beers Consolidated Mines.

dike rock contains no diamonds and that it will be found on further excavation to be of a similar nature to the barren dikes and floating reefs, which occur in the mines at Kimberley.

There is a second small dike about 12 in. wide exposed in Prairie creek at the point where that stream empties into the Little Missouri river. This dike is undoubtedly peridotite and will no doubt be found to join the main body of peridotite at some point which future excavation will disclose.

It may be remarked that the South African pipes have many of these small dikes radiating from them which lead nowhere in particular and which pinch out entirely at a short distance from the pipe.

GENESIS OF THE DIAMOND

Many theories have been advanced and are constantly being advanced to account for the presence or formation of diamonds within these igneous masses of peridotite. It is not within the scope of this article to go into detail with regard to these theories. When it is remembered that we have several hundred of these peridotite pipes in Africa in all of which the peridotites are essentially the same, but in the great majority of which either no diamonds occur at all or so few diamonds occur as to make their recovery unprofitable, one is apt to come to the conclusion that diamonds, like gold, are wherever you find them. One has only to read the chapter on "The Formation of the Diamond" in "The Diamond Mines of South Africa," by Gardner Williams, to come to the conclusion that no one knows, or probably ever will know, just how or where nature has formed the diamond.

THE ARKANSAS DIAMOND AREA

The roughly elliptical area shown in the accompanying map represents as accurately as can be shown at present the peridotite pipe. The major axis which lies in the northeast-southwest direction, is about 2400 ft., while the minor axis is about 1800 ft. The area covered is approximately 60 acres. On a line which lies practically through the three hills shown and which are known as the West, Middle and East hills, are the outcroppings of the hard peridotite referred to as hardbank.

To the south of these hills the ground falls away gradually to the Little Missouri river. This south slope on the volcanic area is composed of a much softer peridotite than that of the hills. It has here weathered in place to a depth which may reach 60 ft., and is known to be weathered for at least 20 ft. This portion of the area which is also the largest portion, being at least 35 acres in extent, can be excavated easily without or with a minimum use of explosives to a depth of at least 20 ft. I estimate that there

is at least 1,500,000 cu.yd. of this material that can be easily and cheaply mined.

Overlying the greater part of the whole area to a depth which does not exceed 1 ft., is a black vegetable soil locally known as "gumbo." This soil contains some peridotite and a mixture of other rocks and soils brought in by the surface waters. A number of diamonds have been found in this soil which were undoubtedly derived from the underlying peridotite.

with inadequate washing machines, and the chances are that as many diamonds were lost in the tailings as were recovered.

Considerable work has been done in the way of clearing up the area of stumps and gumbo and plowing loose the weathered peridotite. During these operations a large number of diamonds were picked up by chance by the workmen. The number of diamonds found in this way is remarkable and is an indication of considerable richness.

THE ARKANSAS DIAMOND AREA

In several places of the pipe area, especially on the three hills, there is a considerable growth of pine and oak timber. The pipe lies in a hilly and broken country intersected by many streams and creeks. The soil in the river and creek bottoms is fertile and the climate healthful.

OPERATIONS

The operations to date have consisted chiefly of haphazard experimental tests of the peridotite from various places on the pipe. These tests were roughly made

BORE HOLES

Three bore holes have been put down with a diamond drill on the pipe area to depths of 79, 184 and 205 ft. These holes are in the peridotite for the entire distance sunk and the peridotite continues beyond the bottoms of these holes to an unknown depth. One of the pipes at Kimberley has been developed down to 3000 ft. with no exhaustion of deposit in sight.

All work on the property is at present suspended until such time as a complete

mining, washing and concentrating plant can be designed and erected, when mining on a large scale will be undertaken.

DIAMONDS PRODUCED

The total number of diamonds recovered from this area to date by chance finds or concentration is 530. Of these 530 stones 505 weighed 217 carats, or an average of nearly 1/2 carat per stone. The largest stone so far found weighs 6 1/2 carats. Most of the stones found are white, while a few are yellow or brown.

A large number of these stones are of good water and of remarkable purity, many being of finer quality than African stones. Three of the stones found have been cut and have yielded beautiful gems

WEIGHT IN CARATS AND COLOR OF THE FIRST 75 DIAMONDS FOUND IN THE ARKANSAS FIELD.

No.	Weight.	Color.
1	2 1/2 - 2 3/4	White
2	2 1/2 - 2 3/4	Light brown
3	2 1/2 - 2 3/4	White

68	1 1/2 - 2 1/4 (found in two pieces.)	
69	1 1/2 - 2 1/4	Brown
70 to 75	6 pieces bort. Total weight 2 1/2 carats.	

which have been valued at from \$60 to \$175 per carat, with an average value for the three cut stones of \$104 per carat.

Taking a parcel of rough, unsorted stones from this pipe it will easily average \$10 or more per carat in value at the present prices of diamonds. This average equals the average of several of the large producing mines of Africa.

CONCLUSION

The engineer who is called upon to report on an undeveloped diamond mine, or property, has the serious obstacle to confront that he can make no definite statements or figures as to what average values may be expected from the working of same. It is impossible to make assays of a diamond mine. Bore holes give only indication of the nature of the peridotite and tell nothing of its richness.

The only way that a definite statement of values can be made is actually to mine, wash and concentrate at least 50,000 cu.yd. of the rock. The greater the amount the more accurate will be the result. Test runs from certain parts of the Arkansas pipe indicate at least 0.21 carats per load of 16 cu.ft., which may be considered a most excellent average if it can be maintained.

In many ways the Arkansas pipe has decided advantages over the South African mines. There is an abundant and nearby supply of water and timber. Fuel and mining supplies are comparatively cheap. Mining should be done here at a cost which would be unattainable in Africa.

Volumetric Determination of Uranium and Vanadium

W. D. Engle, in the *Western Chemist and Metallurgist*, November, 1908, describes a method for the determination of uranium and vanadium which is a combination of Sutton's method and that of other authorities. From 0.5 to 2 grams of the material is taken as a sample, the quantity depending on the amount of uranium present which, if more than 0.25 gram, filtering and washing the uranyl ammonium phosphate will be difficult. The weighed sample is transferred to a 1/4-liter flask and, treated with 20 c.c of dilute sulphuric acid (1:5) and evaporated to fumes of sulphuric trioxide. Organic matter may be removed by the use of nitric acid with the sulphuric acid.

After cooling and diluting to 100 c.c., 3 c.c. of hydrogen dioxide are added to oxidize the uranium and vanadium. An excess of sodium or ammonium carbonate is next added and the mixture boiled a few minutes, partially cooled, filtered and washed. It will generally be necessary

to redissolve the precipitated iron, etc., with dilute sulphuric acid and to repeat the treatment with sodium or ammonium carbonate, combining the filtrates and wash waters. Care at this stage must be used to keep the solution oxidized by the use of hydrogen dioxide.

The combined filtrates and wash waters are made acid with sulphuric acid and ammonium phosphate is added (0.5 to 1 gram). The solution is boiled vigorously to expel the carbon dioxide and made alkaline with ammonia. The thorough removal of the former is essential as the uranyl ammonium phosphate is soluble in ammonium carbonate. This difficulty is in part overcome by boiling the mixture after the addition of the ammonia until the solution has a slight acid reaction, or by the addition of acetic acid.

The uranyl ammonium phosphate must not be filtered from an alkaline solution, as a part of the uranium will probably remain in the solution. With these precautions the uranyl ammonium phosphate may be filtered and washed. Washing with an ammonium-sulphate solution (1:25) helps to prevent the carrying through of the precipitate in the colloidal form.

If the amount of the uranium is very small, a small amount of aluminum sulphate may be added to aid in the filtration and to prevent portions of the uranium from being carried through the paper.

The filtrate, which contains the vanadium, is treated with 10 c.c. of strong sulphuric acid and 2 grams of sodium sulphite. The excess of sulphur dioxide is boiled off, and the solution immediately titrated, hot, with permanganate solution. A twentieth-normal permanganate is recommended rather than a stronger solution. The iron factor of the permanganate multiplied by 0.9159 gives the vanadium factor, or by 1.631 gives the V₂O₅ factor.

The uranyl ammonium phosphate is dissolved with dilute sulphuric acid, granulated zinc of known purity is added and the reduction continued for 45 minutes. The solution is decanted from the zinc and the zinc washed. The solution with the wash waters is titrated with the permanganate solution. It is important that this be not stronger than twentieth-normal, as the atomic weight of uranium is so great that it gives a large factor for the permanganate. The iron factor of the permanganate multiplied by 2.133 gives the factor for uranium, or multiplied by 2.5167 gives the factor for U₃O₈.

This method, says the author, has been checked against pure uranium and vanadium salts with satisfactory results. None of the elements commonly found in ores interferes with it. The method has been repeatedly checked by the gravimetric methods with results that agree closely, and the saving of time is considerable.

New 506-ft. Chimney at Great Falls Smelter

The Largest Chimney, Both in Size and Capacity, in the World;
Flue Dust Caught by Network of Wire Suspended in Dust Chamber

BY EDWIN HIGGINS

The new chimney at the Great Falls smelter of the Boston & Montana Consolidated Copper and Silver Mining Company was topped out Oct. 23, 1908. This chimney is 506 ft. in height above the foundation and is the largest, both in size and capacity, in the world. The smelter, shown in plan in Fig. 1, is situated on the north bank of the Missouri river, about three miles from Great Falls, Mont. The plant, which consists of reverberatory and blast furnaces, McDougal roasters and converters, has a capacity of 4500 tons of ore per day.

Additions made to the plant in recent years have increased the production of furnace gases, so that at times as much

consequence of this its interior was badly eaten and disintegrated. Accordingly it was decided to build a new system of flues and a new chimney, the latter to have a capacity of 4,000,000 cu.ft. of gases per min. at a temperature of 600 deg. Fahrenheit.

SITE AND FOUNDATION

The site chosen for the new chimney was 2000 ft. back of the furnace plant, the elevation here being 246 ft. above the charging floor of the furnaces.

It was first determined to excavate to a depth of 30 ft. for the foundation, but when 22½ ft. of depth had been attained, it was determined by tests that it was

shows the first 25 ft. of the chimney, and two of the flue openings.

THE CHIMNEY

The chimney proper has an octagonal base 46 ft. high with a taper of 8 per cent. Above this point the section is circular, the first 180 ft. above the base having a taper of 7 per cent., the next 100 ft. 4 per cent., and the remaining 180 ft. 2 per cent.

The chimney was built in 23 sections; 19 of these are above the octagonal base. The thickness of the chimney wall varies from 66 in. at the base to 18½ in. at the top. The outside diameter at the base is 78½ ft., and 53¾ ft. at the base of the cap. The inside diameter at the base is

FIG. 1. GENERAL LOCATION PLAN OF SMELTER AND FLUE SYSTEM, AND SECTION THROUGH CONNECTING FLUE AND DUST CHAMBER

as 2,000,000 cu.ft. of gases per min. are made. The old chimney is situated about 1500 ft. back of the plant, and the gases were led to it through large masonry flues buried to the level of the intervening ground. This chimney is 20 ft. in diameter and 185 ft. above ground; being situated on a slope rising gently from the smelter site, its top is about 400 ft. above the level of the blast-furnace floor. Under ordinary conditions its capacity is only about 700,000 cu.ft. of gases per min. This lack of capacity in the old chimney at times caused a serious loss in flue dust; moreover, its brick and mortar construction had exposed it to the action of the acids which formed in wet weather. In

unnecessary to go deeper. The ground in which the excavation was made is hard shale. The foundation consists of an annular mass, the circular inner edge of which is 47 ft. in diameter at the bottom and the octagonal outer boundary 103 ft. across flats at the footing level, tapering to 64 and 81 ft. diameters at the top of the concrete. The foundation was constructed of 1:3:5 slag concrete. The sand and stone were obtained from the smelter furnaces. In the work of construction 5200 bbl. of cement, 2000 cu.yd. of sand and 4000 cu.yd. of slag were used; the cost of materials and construction was in the neighborhood of \$50,000. Fig. 2 shows the completed foundation. Fig. 3

66½ ft.; at the top, 50 ft. In the base of the chimney are four flue openings. Fig. 6 is a view of the old and new chimneys, 185 ft. and 506 ft. high, respectively.

CHIMNEY LINING

As a protection against the corrosive effects of the furnace gases, the chimney is lined with 4-in. radial perforated blocks, acid proof, installed in sections. Acid-proof mortar, made of silicate of soda, asbestos wool and other ingredients, was used. The chimney was first completed and the lining put in afterward. There is a 2-in. air space between the lining and the chimney proper, and every precaution is taken to prevent the gases

or metalliferous dust from entering the air space. In laying the cap for the protection of the top of the chimney from the action of acids which might form, special terra cotta blocks with interlocking sections for the joints were used. These blocks, or tiles, are laid in and pointed up with acid-proof cement mortar.

PROTECTION AGAINST LIGHTNING; LADDERWAY

Protection against lightning is afforded by a lightning rod of 16 points, which projects 5 ft. above the top of the chimney. These rods are made of 1-inch round copper, coated with lead and tipped with $\frac{1}{4}$ -in. platinum points. Encircling the

guards and rungs are coated with lead for the upper 100 ft.; below this they are painted.

FLUE AND DUST CHAMBER

The connecting flue and dust chamber are shown in plan and section in Fig. 1; Figs. 7 and 8 give an idea of their construction. Between the smelter and the dust chamber the flue is of rectangular cross section, 33x21 ft. Between the dust chamber and the chimney the dimensions are 48x21 ft. The whole flue system is framed in steel, with steel columns and cross-beams; the walls and roof are made of the same material as the chimney. All steel work is

tracks over which are run trains of electrically operated dump cars; these cars receive the contents of the hoppers. The tracks are shown in Fig. 8.

The dust chamber is 176 ft. wide and 478 ft. long with a height of 21 ft. in the clear. The basement story is 12 ft. high. The dust chamber is divided into two parts so that either side can be shut off and made accessible. For this purpose heavy cast-iron dampers are provided, operated by means of motors. There are no wires or hoppers in the connecting flue proper, between the dust chamber and the stack. The blast-furnace flue is provided with a hopper bottom, but no network of wires.

FIG. 2. FOUNDATION FOR CHIMNEY

FIG. 3. FIRST 25 FEET OF CHIMNEY

FIG. 4. DETAIL OF TOWER AND SCAFFOLD SHOWING TRUSS

FIG. 5. DETAIL OF TOWER SHOWING ELEVATOR POSTS

chimney a few feet below the top is a horizontal copper ring, from which two $\frac{3}{4}$ -in. stranded copper cables lead to the ground; this ring is connected to the lightning points. The copper ring and cables leading to the ground are coated with $\frac{1}{8}$ in. lead 100 ft. from the top as a protection against acid. The copper cables leading to the ground terminate in 3-ft. ground plates, which are buried at a distance from the chimney.

On the outside of the chimney, built into the brickwork, is a ladderway consisting of one-piece rungs of $\frac{3}{4}$ -in. round iron 12 in. wide, and one-piece guard loop of the same material, 30 in. wide. The rungs stand 6 in. clear of the wall. The guard loops are 18 in. out from the rungs. Both

exposed, both inside and outside. The dry gases have no corrosive action on the steel framework or the walls.

Fastened to the bottom of the I-beams of the roof of the dust chamber is a heavy copper wire net, from which is suspended 1 in. iron wires about 4 in. apart, forming a suspended network. The gases in passing through the chamber come in contact with the suspended wires and deposit thereon the suspended flue dust. All the wires below their upper support are connected with a shaker beam operated by a motor outside the walls of the dust chamber. By this means the dust clinging to the wires is shaken off and deposited in the hoppers provided in the floor of the dust chamber. Under this floor are 22

THE SCAFFOLD AND TOWER

In the design and construction of this flue system and chimney the engineers and contractors were confronted by many problems. Probably the most important problem of the construction, as far as the contractor was concerned, was the efficient and safe handling of the 17,000 tons of blocks and mortar required in the work. The problem was to keep the men continually supplied with materials and at the same time provide safe conditions under which they might work at great heights. The inside diameter of the chimney was too great to permit of a single-stick system to support the working floor, or a system of floor beams which could be carried up, as is usual, as the chimney pro-

gressed. The scaffold had to be of such a design that after the working hours of the bricklayers, the floor system could be raised in the least possible time and a new scaffold prepared before the following morning. Provision for a sufficient number of elevators and their safe and speedy operation in handling 200 tons of material a day was also a factor in the scaffold problem.

A 12-post square tower of 10x10-in.x16-ft. fir timbers was finally decided upon. The construction and arrangement of this tower is shown in Figs. 3, 4 and 5. At each flue opening two of these 10x10 posts were placed to form a set of guides within which to operate a 6x9-ft. elevator. Strips of 2x4-in. oak, spiked to the 10x10-in. timbers, served as guides. The distance between elevator posts was about 7½ ft. The center span between two opposite posts was 30 ft. The catheads spanning the elevator posts were built of two 3x10-in. fir timbers, reinforced longitudinally with ¼x6-in. steel plates. The 3x10 timbers were spaced 2½ in. apart and between them operated the 14-in. sheaves in the iron boxes. These sheaves carried the elevator cable of ¾ in. cast steel, operated in three cases by electric hoists at a speed of 300 ft. per min. The fourth elevator was run by a steam hoist of 35 h.p., at a speed of 600 ft. per minute.

For rapid change of scaffold, it was necessary that the elevator heads be designed so that they could be easily lifted off the 10x10 timbers, and when another post had been added, quickly replaced. For this reason the catheads of 3x10 timbers carrying the head sheaves were supported at their bearing ends with 10x9x¼-in. steel plates; one drilled to take a ¾-in. dowel pin from the top of the 10x10 posts, the other having a slotted ¾-in. hole to take up any slight variance in distance between the posts.

The ¾-in. dowel pins and plates held the elevator heads in place, with no further fastening, without accident, throughout the whole construction of the chimney. They were handled off and on by 18-ft. poles and a set of double blocks.

Throughout the tower the main posts were braced with 2x6-in.x16-ft. sway braces, bolted. Each section of post was doweled by a ¾x10-in. pin and spliced with 2x10-in.x5-ft. pieces, bolted. The sash bracing, which also formed the ledgers supporting the 8x8 timbers of the main scaffold, consisted of 3x10-in.x12-ft. timbers bolted to the posts. One end of the 8x8 floor beams of the main scaffold rested on the finished wall of the chimney; the other end was notched around the edge of the post and rested on the 3x10 against the post. The whole system bolted.

Spanning the 8x8 longitudinal main timbers were 6x6-in. floor beams, and on these were laid the 2x10-in. scaffold plank,

forming a floor seven planks wide around the whole interior of the stack next to the wall, leaving the center open.

The maximum load on each post was calculated to be 18 tons. Being inside the stack, they were exposed to no wind pressure, except at the bottom at the flue opening for 36 ft., and that portion extending above the brickwork. It will be seen that the eight elevator posts which were carried to a height of 516 ft. would have one side toward the elevator unsupported in that direction. To complete the rectangle and protect the unsupported side would have required an additional four posts with sway and sash bracing in the center

during the working hours of the bricklayers and were ready to hoist into place during the hours of raising the scaffold. Since they occurred at only every 30-ft. interval, it was at every other raise of the main scaffold that they became necessary. With a four-post system in the center, it would have been necessary to erect the posts and all their bracings at each raise of the scaffold; and the work would have to be done after the bricklayers' hours. The time consumed in raising the scaffold was between three and four hours, so naturally all the preparation for raising that could be made during the bricklayers' hours was that much saved.

FIG. 6. THE NEW AND THE OLD CHIMNEY

of the stack. This would mean, at each raise of 17 ft. of the main scaffold, an operation necessitating speed, the raising of four 10x10 posts and the placing of all the extra bracing. To avoid this and prevent the crushing in of the posts, a system of four intersecting trusses was introduced every 30 ft. spanning the elevator posts. These were bolted together at their intersections and their upper and lower chords with connecting members, so designed as not to take a vertical load, but to resist a racking strain. These trusses were all framed and put together

On the main scaffold, when the wall had been built 6 ft., were placed a system of wooden horses, and a second floor built on them. From this point 6 ft. more wall was built, after which the men worked from benches 3½ ft. high and built 5 ft. more of wall, making 17 ft. from one main scaffold.

At the 17-ft. height a second set of floor beams was put in, a new floor over these leaving the scaffold below intact so there were always three floors in place. The same wooden horses and benches were then used from this floor until the floor

below was stripped, after which it was used again above. In this manner a new scaffold was erected every 17 ft., the original floor being carried to the top, the heavy floor beams alone being left behind as braces for the main truss.

PLUMBING THE STACK

The method of plumbing the stack was unique. A 5-ft. plumb rule, set to the proper batter, was used on the outside of the stack. Each third course was plumbed around as the blocks were set in place.

The chimney was designed and erected by the Alphons Custodis Chimney Construction Company, of New York. The flue and dust chamber were designed by the Boston & Montana company.

Comparison of the Iodide, Cyanide and Electrolytic Methods for Copper

J. W. Howson (*Min. and Sci. Press*, Aug. 22, 1908) has compared the accuracy of the iodide, cyanide and electrolytic methods for the determination of copper.

Finely divided metallic copper or the sulphide is readily oxidized and solution then readily takes place. If this hydrogen-sulphide treatment is omitted the results by the iodide or cyanide methods are usually lower than by the electrolytic method provided that the electrolytic precipitation can be accurately made from a simple solution. There is also always a loss in filtering a copper solution, sometimes amounting to several hundredths of 1 per cent., which amount is retained by the filter paper even after many washings.

Appreciable amounts of iodine are liberated by impurities in the precipitated copper or in the reagents in using the iodide method and cause high results. This error, it is true, may offset the loss in filtration, but the counter-balancing is uncertain and is dependent upon the carefulness of the analyst.

Comparing the iodide and cyanide methods, the cyanide titration is rougher, much is left to the judgment of the operator, and the accuracy depends upon the closest adherence to the same working conditions as to bulk, foreign salts, and free ammonia as prevailed in the standardization.

The electrolytic method on simple ores gives accurate results, but unfortunately there are many ores which contain interfering elements. Except in the case of great excess of iron salts, the errors are nearly all positive and yield high results.

FIG. 7. FRAMEWORK OF CONNECTING FLUE

On windy days, when a plumb bob was useless, the work was done from a set of levels fastened to a brass plate at the top of the plumb rule. By this means work could be carried on in a high wind. At times when the wind was blowing almost a gale, no delay was occasioned, although it took two men to hold the rule over the side of the stack.

In order to check the workmen, four transit points were set from $\frac{1}{2}$ to $\frac{3}{4}$ of a mile away. These points were established before the stack was started, so that the transit line intersected the center of the stack. During the progress of the work this center from the foundation was thrown by means of instruments to the top of the stack and the center obtained on top by means of the intersection of two strings. The perimeter was then tramed from this center. On calm days a check was taken to the center plug by means of a 30-lb. plumb bob. At no time was the center off over an inch, and at completion of the chimney no variation whatever could be determined.

As a means of communication between the men above and those below, a system of tin speaking tubes was maintained at each elevator well. This was fastened to one of the posts and the tubes extended with each raise of scaffold. The elevators were operated upon signals by electric bells, the push buttons being carried up with the scaffold.

FIG. 8. LOWER FLOOR OF DUST CHAMBER

The customary procedure in cyanide and iodide assays is to precipitate the copper on aluminum foil from a sulphuric acid solution. This separation is not complete, and may often explain the inaccurate results obtained. The presence of nitric acid, due to incomplete expulsion by sulphuric acid, or the presence of large amounts of iron salts is the cause of the incomplete separation, which source of error may be overcome by precipitating the last traces of copper with hydrogen sulphide and using hydrogen-sulphide water in subsequent washing of the precipi-

The removal of the interfering elements requires a high degree of skill, and for these reasons the iodide method is preferable on impure ores. As between the three methods the electrolytic method is preferable where no previous separation of the copper from interfering elements is necessary, otherwise the iodide is better. The danger of error in the standardization of the iodide solution is more than offset by the loss of copper attending the removal of the cathode from the electrolyte. The cyanide method is the least satisfactory.

The Coalfields of the United States

Production of Coal, Including Waste, up to January 1, 1908, Was
10,218,000,000: Estimated Original Supply, 3,157,243,000,000 Tons

2000 BILLION TONS AVAILABLE

The accompanying map, redrawn from one prepared by the U. S. Geological Survey, shows the coalfields of the United States as their outline is now known and the kinds of coal they contain. Up to the present time it has not been possible to prepare so accurate a map, on account of lack of data regarding the shape and extent of many of the western coalfields and the quality of their coal, but during the last few years a large amount of such information has been obtained in connection with the classification and valuation of coal land in the public land States of the West. In carrying on this work the Geological Survey has mapped most of the important coalfields and has tested many of the coals, so that information now at hand seems to be fairly complete. There is still, however, considerable uncertainty regarding the extent and value of some fields containing low-grade coal or lignite. This is particularly true of the lignite fields of the Gulf province, except those of Texas, in which there has been considerable development and exploitation. Little information is available regarding the lignite areas of south Dakota and the lignite and sub-bituminous fields of the Fort Union region, in eastern Montana. The extent and value of the coal beds of the Assiniboine region, in north central Montana, as well as those of the isolated Tertiary lake basins of the mountainous parts of the State, are also matters of speculation.

Information as to the extent, the value, and even the existence of the coalfields of the Pacific coast is very meager. California and Oregon probably have greater coal resources than those now known, but the beds in these States are generally of low-grade coal and are undeveloped. The fields of Washington doubtless embrace a much greater area than that shown on the map, but they are so covered by glacial gravel and heavy timber that it is impossible to determine their extent. Probably many of the areas represented on the map are really connected in a broad belt of coal-bearing rocks along the west slope of the Cascade range.

Little is known regarding the occurrence of coal or the extent of the fields in southern and southeastern Utah, where there are probably many areas of coal-bearing rocks but little coal of commercial importance.

On this map, for the first time, an attempt has been made to represent the coal

in the deep basins or synclines of the Rocky Mountain States, where there is every reason to suppose that coal exists, although it is so deeply covered by later sediments as to be accessible with great difficulty if at all. The most important of these basins are the San Juan River basin of New Mexico and the Colorado, the Uinta basin of Colorado and Utah, the Green River basin of Wyoming and Colorado, and the Bighorn basin of Wyoming. None of the basins and troughs of the eastern part of the country is like these western basins, except, possibly, the central part of the Appalachian trough in West Virginia and a part of the Michigan basin, but both of these are comparatively shallow, and all of the coal they contain may be regarded as accessible.

CHARACTER OF THE COALS

From a commercial standpoint the most important feature of the map is the distinction between the various grades of coal. The Geological Survey recognizes the following six classes: (1) anthracite, (2) semi-anthracite, (3) semi-bituminous, (4) bituminous, (5) sub-bituminous (black lignite), and (6) lignite.

In almost all the western fields there is a transition from low-grade to high-grade coal in the direction of the principal mountain uplift. In the San Juan River region the coal changes from sub-bituminous in the southern part to bituminous on the flanks of the San Juan mountains, the transition in the field being gradual and not sharp. In the Uinta basin the coal is bituminous, and of fairly uniform quality in all parts of the rim. In the Green River basin most of the coal is sub-bituminous, but some around the Rock Springs dome in Wyoming is bituminous, as is the lower coal in the eastern part of the Yampa field in Colorado. In the Bighorn basin the coal does not differ much in composition from place to place; in general it is better on the southwestern side of the basin, but even there it hardly reaches the grade of bituminous. In the Fort Union region there is a decided change from the brown lignite of the North Dakota portion to the sub-bituminous coals of the Sheridan district in Wyoming. This change is gradual, affecting a wide region in eastern Montana.

GEOLOGIC AGE OF THE COALS

The geologic age of the coal-bearing rocks of the United States ranges from

Carboniferous in the eastern and interior provinces to Miocene (Tertiary) in California and other places on the Pacific coast. In a very general way the quality of the coal varies with the geologic age of the coal beds, but there are so many exceptions that such a generalization has little value.

In the main the best coals of the country are of Carboniferous age and are found in the anthracite and Appalachian fields; also in the northern, eastern, western, and southwestern regions of the eastern and interior provinces. In this broad area the coals of higher grade occur in the anthracite region, along the eastern front of the Appalachian region, and in the Arkansas fields of the western region near centers of great disturbance and mountain building.

In the Atlantic Coast region a number of basins of Triassic rocks contain workable beds of coal. In the early days of the colonies these were of great importance, but later they fell into disuse and are now practically abandoned.

The lignites of the Gulf province are of Eocene (Tertiary) age and are of low grade except in the vicinity of Laredo, on the Mexican line. Those of the Eagle Pass region are of better grade and are decidedly older, belonging to the Cretaceous system.

In the Rocky Mountain and Northern Great Plains provinces the coal-bearing rocks range in age from Lower Cretaceous to Eocene (Tertiary). The former occur in the Great Falls and Lewistown fields of the Judith basin, central Montana, and in the Black Hills region, Wyoming. These rocks are of Kootenai age, the age of the rocks of the Crows Nest Pass and other important fields of Alberta.

Upper Cretaceous rocks carry most of the coals in the San Juan River and Raton Mountain regions of southern Colorado and New Mexico, as well as those in most of the scattered fields of New Mexico. In the other fields of Colorado and Utah almost all the coal beds so far known are of this age. In Wyoming, Upper Cretaceous coals are present in the Hams Fork, Green River and Bighorn Basin regions, and in the Hamá and other smaller fields. In Montana they are limited largely to the Yellowstone and Assiniboine regions and to the Bridger field, in Carbon county.

The great expanse of coal of the Fort Union region of North Dakota, South

Dakota, Montana, and Wyoming is of Eocene (Tertiary) age. Coals of the same age occur in the Bull Mountain field, on Musselshell river, and in the Red Lodge field, on the southern boundary of Montana. Eocene coals also occur in the Green River basin east of Rock Springs, in the center of the Hanna field, and in certain parts of the Hams Fork region, in Wyoming.

The mountain basins in the western part of Montana, as well as some in Idaho, are of Tertiary age, although few of them have been mapped and the coals of only a few have been examined.

In the Pacific Coast province all the coals are of Tertiary age, though some of them have been locally metamorphosed into anthracite by intrusions of igneous rock. The Washington coals, as well as those of the Coos Bay field in Oregon, are Eocene; those of west-central California—at least those in Stone cañon, Monterey county—are Lower Miocene.

ESTIMATED TONNAGE OF THE VARIOUS FIELDS

During the last few years considerable attention has been given to the need of conserving the mineral fuels of this coun-

try of the West, that will afford the basis for a fairly trustworthy estimate of the tonnage of coal yet remaining. These western fields, however, except those of Washington, are of small extent, and the uncertainty as to their content has little effect on the aggregate amount.

The latest available estimate of the total original tonnage of the coalfields of the United States, exclusive of Alaska, was made by the Geological Survey in 1906. This estimate gave 2200 billion short tons as the total original content of the fields, but was confessedly made without adequate information, since little was known at that time regarding many of the most important fields of the Western States. With the increased information at hand regarding these fields, it seems opportune now to present an estimate considerably larger than that made two years ago. Part of this difference is due to increase in information, and part to an increase in the limit of depth to which coal beds may be worked.

The limit of workable depth in the estimate here given is based on actual mining conditions abroad, especially in Belgium. This limit is 3000 ft. for coal and 1000 ft. for lignite. Twenty inches is regarded as

content available for future use of nearly 2000 billion tons. The rate of consumption cannot be predicted with certainty, but if the rate of increase that has held for the last 50 years is maintained, the supply of easily available coal will be exhausted before the middle of the next century.

Coalfields of the Big Horn Basin

A party of coal geologists of the United States Geological Survey have been at work during the summer in the examination of the coal deposits of the southeastern part of the Bighorn Basin. The party consisted of E. G. Woodruff and Max A. Pishel, of Washington, D. C., Roy L. Nelson and J. H. Cather, of Lincoln, Nebraska and Jesse Gallaway, of Bloomington, Indiana. The region examined by these men lies between Nowater creek and Bighorn river. Preliminary surveys had shown that outside of this area no workable coal beds are to be found between the mountains and Bighorn river, south of a line running east from the mouth of Nowater creek. In the area where coal was known to occur, the geologists made careful examination of the coal deposits, measuring the thickness of the coal beds, determining their extent and gathering such other information as might aid anyone who wished to develop mines.

"The most promising beds of coal," said Mr. Woodruff, who was in charge of the work, "occur along Nowater creek and north of Kirby creek, near Bighorn river. These later deposits are the eastward extension of the beds mined at Gebo and Crosby. Less important deposits occur at several places along Nowater creek, also near the head of Bud Kimball Draw, and on the upper branches of Big Cottonwood creek.

WATER AND GAS OCCUR ONLY IN SMALL QUANTITIES

Those coal beds generally are not so thick or extended as those found elsewhere in the Bighorn Basin. In fact, they seem to be too limited to warrant the construction of a railroad for their development alone. There is sufficient coal, however, to furnish an abundant and permanent supply to the ranchers living within reach of the various beds. The examination shows too that the beds dip at favorable angles for mining and that water and gas occur in such small quantities that no difficulty will be experienced from these elements which are often troublesome in coal mines.

The geologists class this coal as sub-bituminous. This means that the coal is better than the brown lignites mined at many places in the West, but not so good as the bituminous coal of Pennsylvania or West Virginia. The coal in the southeastern part of the Bighorn Basin is about the same grade as that mined at Gebo and

try for the use of future generations. Few persons were in possession of data that would enable them to make an estimate of the amount of coal yet remaining in the ground, and no one knew whether or not the present growing consumption would continue indefinitely; consequently there has been a general feeling that the supply of coal in the United States is inexhaustible, and that the present generation need give no thought to this troublesome question.

The uncertainty regarding future consumption still exists, but data are now at hand, except for certain little-known fields

the minimum minable thickness of bed for coal and 3 ft. for lignite.

The table shows the size of areas represented on the map, in square miles; the kind of coal; the production in 1906; the total production to date, including estimate of production for 1907, to which is added 50 per cent. for waste in mining; the estimated original tonnage; the estimated amount remaining in the ground at the present time.

The figures given show that the area of the more accessible coalfields of the United States is about 327,000 square miles, and that they carry an estimated

Crosby. It contains a small per cent. of ash, a low per cent. of sulphur and is non-coking. The coal ignites readily and burns freely. Such coal is best suited for domestic purposes, but, with proper grates and drafts, can be successfully used for steaming.

Samples of the coal were sent to the laboratories of the Geological Survey for analysis, so that the quality of this coal may be known exactly and compared with coal from other fields.

The work done this year completes the Survey's investigations of the coal deposits of the Bighorn Basin. Last year one party surveyed the west side of the Basin and another the area lying to the north-east. Reports on the areas mapped last year are now being printed at the Government printing office in Washington, and will soon be ready for free distribution. Anyone desiring these reports can obtain them by addressing the Director, U. S. Geological Survey, Washington, D. C. The report on the area surveyed this year will be written by the geologists in Washington this winter, and when published will be sent to anyone wishing to know about this coalfield.

The Tariff Hearings at Washington

SPECIAL CORRESPONDENCE

Considerable numbers of briefs continue to be filed with the House Ways and Means Committee including many that deal with the duties on metals and minerals and their products.

COAL AND IRON

In one of these briefs C. M. Freeman, for the National Grange, asks that forest, coal and iron products be placed on the free list. The Harrison Supply Company, Boston, Mass., asks abolition of the duty on iron sand.

I. W. Kuhn, Pittsburg, Penn., writes in advocacy of a policy of reciprocal free coal with Canada. The Fairmont Coal Company, of West Virginia, opposes free coal unless coupled with a reciprocity provision. The National Forest Conservation League has filed further argument and a mass of correspondence favoring removal of the duties on lumber in the interest of better conservation of resources. H. L. Stowell, Ellensburg, Wash., has filed argument in favor of the free admission of Canadian coal and lumber. Hon. Jas. Kennedy transmits a number of protests against the granting of drawbacks on tinplate. Ralph H. Stearns, New York, asks reduction or removal of the duties on steel.

LEAD AND ZINC ORES

A. B. Cockerill, Nevada, Mo., files a supplemental argument against the proposed duty on zinc ore. Edward Brush, of the American Smelting and Refining Com-

pany, files estimate of 81c. to \$1.48 per ton as the cost of laying down a ton of 5 to 14 per cent. lead ore at the mouth of one of the four largest mines in Mexico controlled by his company. He also corrects some points in his previous testimony before the committee.

RARE METALS AND ALLOYS

Charles Engelhard, New York City, asks that rhodium and ruthenium be placed on the free list along with platinum, iridium, palladium and osmium. W. B. Klee, Damascus Bronze Company, Pittsburg, Penn., submits correspondence showing that the Treasury refuses to make phosphor-copper and tin dutiable unless phosphorus is the element of chief value. R. F. Long, New York City, importer of phosphor-manganese and silicon-copper argues against any duty on phosphor-copper and tin.

MINERAL PAINTS

Peter Zucker, New York, "in behalf of the manufacturers of dry colors of the United States" submits a dry-color schedule providing that Berlin, Prussian, Chinese and other blues containing ferrocyanide of iron remain at 8c. per lb.; that all chromium colors in which lead and bichromate of potash are used remain at 4.5 per lb.; that in either of the foregoing cases if there be a reduction a corresponding reduction in the constituents (potash, lead, etc.) be made; that colors containing quicksilver be raised from 10 to 15c. per lb.; that white sulphate of zinc now dutiable at 1.25c. per pound be particularly maintained at its present rate; that in case of any reductions in the tariffs on colors there be corresponding reductions on a large number of articles including barytes, white lead, whitening, oxide of zinc, quicksilver, etc. F. A. Reichard, New York, asks that ochers, umbers and siennas and dry zinc be free of duty; that orange mineral be reduced to 1.55c. from 3.375c.; red lead to 0.99c. from 2.875c. and white lead to 0.93c. from 2.875c.; that ultramarine blue be reduced by an indeterminate amount; natural oxides of iron 40c. per ton; artificial oxides to 15 instead of 30 per cent. English vermilion be taxed at rates varying from 5c. (the present duty) to free entry. These views are supported by a large collection of letters from paint-makers stating the rates they prefer and generally concurring with the above recommendations. J. Lee Smith & Co., New York City, urges maintenance of the present classification of ochers, sienna and umber.

PHOSPHATES AND FERTILIZERS

J. L. Hills, director Vermont Agricultural Experiment Station, asks that all fertilizers be admitted free. E. H. Jenkins, director Connecticut Agricultural Experiment Station, asks free entry for sulphate of ammonia. Wm. P. Brooks,

director Massachusetts Agricultural Experiment Station, asks that guano, sulphate of ammonia, basic slag-meal and land plaster be admitted free. Similar views are taken by the directors of a number of other New England agricultural experiment stations.

MISCELLANEOUS

Watson Brothers, Boston, Mass., importers of mica, favor removal of the present ad valorem rate of 20 per cent. and retention of the existing specific duty.

Hon. W. P. Brownlow files a letter from H. E. Graves, Bristol, Tenn., asking a duty of \$5 per ton of 2000 lb. on crude barytes, \$12 per ton on manufactured barytes and \$25 per ton on barium salts, precipitated barytes and their compounds.

The Wadsworth Stone and Paving Company, Pittsburg, asks that the duty on asphalt be raised. Jno. W. Langley presents a letter from the Albany Mining & Investment Company, Monon, Ky., and asks a reasonable tariff on fluorspar. Thos. H. B. Haase, Princeton, Ky., asks a duty of \$1 per ton. The Sunny Brook Lead and Fluorspar Company, asks a tariff of \$3 per ton. The O'Rourke-McCabe Plastering Company, New York City, asks free entry for Nova Scotia gypsum. The Angels Marble Company, Vallicita, Cal., asks a reduction of the tariff on marble. The Chavant Manufacturing Company, Jersey City, asks that plastilena be placed in the tariff act as a classified manufactured article dutiable at 50 per cent. The American Emery Wheel Works, Providence, R. I., asks to have pulverized corundum placed on the free list.

New Method of Preparing Sand for Leaching

A new method for removing slime and water from gold-bearing sand, devised by W. A. Caldecott, has been in use at the Knights Deep and the Simmer & Jack Proprietary mines for some time, and is being adopted by the East Rand Proprietary Mines (*South African Mining Journal*, Sept. 12, 1908). The sand and slime are run to conical classifiers; the sand and water coming off at the bottom runs to a slowly rotating horizontal vacuum filter table. The moist sand is scraped off from the table by a fixed plow into a hopper where it is mixed with a constant flow of cyanide solution. The mixture of sand and solution is then transferred to a large vat where it is leached in the ordinary way. This vat before receiving sand is filled with solution, and the overflowing solution is returned to the hopper. By means of this process, costs have been reduced and the extraction increased as the sand is more leachable.

The London Copper Market in 1908

SPECIAL CORRESPONDENCE

January disclosed an increase of 1922 tons in the visible supply, bringing the total up to 19,710 tons. There was, however, considerable activity in trade, chiefly with India; and confidence was further inspired by the improved outlook in American finance, as also by the early reduction of the official English bank rate from 7 to 6 per cent. Standard copper, which had closed in December at £60 15s. for cash warrants, opened with an advance of 5s., advancing to £62 10s., with three months' warrants touching £63 10s.; and the price of Lake Superior brands advanced to 13¾@13½. This advance was partly lost by the early intervention of bears, whose operations were prompted by the aforesaid statistics; and the market remained uneventful for the first week or so. On Jan. 9 renewed activity was inspired by increased firmness on the part of American producers, coupled with improved American demand. Consumers and speculators bought freely, thereby carrying the price of three months' warrants up to £64 15s., which price was registered on Jan. 15; Indian and Chinese orders contributing to the improvement. Sales were largely covered with American supplies, whereby the American producers were relieved of substantial quantities and were accordingly firm in holding for full prices. The London market suffered some temporary relapse caused by bear sales, but quickly recovered in virtue of good trade. On Jan. 21 Wall Street began to display new signals of distress which induced a decline, which even reductions in the European bank rates could not arrest. The inertia thus produced became gradually more pronounced on the rumor of certain mines being reopened, notwithstanding the already ample scale of production. The closing days of the month witnessed restricted business and a gradual decline down to £61 2s. 6d. for cash warrants, and £61 15s. for three months; the American quotation being meanwhile reduced 12½ points.

February found the market devoid of any feature of interest to stimulate operations in either direction. The tendency soon became weak in response to unpromising advices from the United States, and values declined accordingly to £60 7s. 6d. cash, and £61 forward. These figures prompted bear covering, which quickly raised the latter value to £62 15s., which price was paid on Feb. 5. Heavy sales followed, coinciding with disappointing reports from the consuming centers and complications in the American industrial situation. An almost uninterrupted decline carried values down until on Feb. 19

three months' warrants touched £56 12s. 6d.; American prices being meanwhile reduced in proportion. Much of the selling on the London market was understood to be for American account, and was further prompted by grave apprehensions of trouble in the British shipbuilding and engineering industries. On Feb. 20 better news from Wall Street, and a brighter outlook in the labor question, caused a rally which carried three months' warrants to £59 10s. During the decline, however, bears had covered their commitments and the bull account now predominated. Important business with consumers in France and Germany infused some genuine vitality into the market, as also did persistent orders from China—chiefly for electrolytic. American business, however, remained very slack, and the New York price had drifted down to 12c. before any improvement set in. The remainder of the month saw fluctuations within narrow limits, and copper shares were strengthened by rumor of impending resumption of work at the Anaconda and other mines in Montana. The official price of sheet copper was advanced £2 per ton. The closing prices of Standard were £58 for cash warrants, and £58 12s. 6d. for three months.

In March, recent firmness was early dispelled by official announcement that the mines and smelters of the Amalgamated company would resume work to their full capacity. The news was not unexpected, but its effect was nevertheless depressing, and was followed by successive cuts in New York down to 12.37½@12.50c., or within a fraction of the lowest recorded in recent years. On the other hand some confidence was imparted by improved tone in the stock and share markets; and fluctuations were, therefore, within narrow limits, notwithstanding the restricted operations of consumers and the eager competition for their orders. On March 12 some revival was manifest, due to revived demand, especially for electrical work, and the low ebb to which consumers had allowed their stocks to diminish. A similar movement took place in America where the revival, though rather feeble, was none the less welcome. A good inquiry from Indian markets and a more cheerful tone on the Stock Exchange also imparted strength. The price of three months' warrants accordingly advanced from £58 2s. 6d. on March 11 to £60, which was paid on March 16. A temporary reaction then set in, mainly induced by bear selling; but sentiment was very diverse, and confidence was somewhat inspired by reduction of the official bank rate of interest to 3 per cent. By this time American producers had been largely relieved of surplus stock and were accordingly firmer in their quotations, and various industrial enterprises which had been retarded during financial unrest were again under consideration. The fourth week of the month witnessed a

large speculative business in copper and tin, the former being apparently connected with operations in copper mining shares; but the consumptive trade was not so encouraging—at least in Europe, where consumers had by this time covered their requirements and were now holding aloof. It was better in America where electrical industry prompted an improved demand and producers had raised their prices gradually to 13¾c. The London market improved in sympathy therewith to £62. Thereafter followed a distinct reaction primarily due to weakness in American shares and to slackening of trade inquiries. The closing prices were £59 17s. 6d. for cash warrants, and £60 5s.@£60 7s. 6d. for three months.

April opened with a flat market, holders having become impatient in face of the steadily growing production of the metal. For a time speculators absorbed offerings fairly well, and prices suffered only moderately; but reduced quotations from New York soon deepened the prevailing depression. Consumers were apathetic and business was restricted. American demand was further checked by recurrence of financial instability. On April 10 prices had fallen to £57 15s. cash, and £58 5s. three months; while leading American producers were readily meeting demand at 13c. for electro, and even this reduced price was undercut by some of the lesser producers. There were also rumors of wholesale reselling for Chinese account, some unshipped orders being certainly countermanded. The next feature was a recovery induced by covering of short sales, and a concerted buying movement which coincided with a bull campaign in copper mining shares, whereby values were carried up to £58 12s. 6d. and £59 respectively on April 16. On the resumption of business after the Easter holidays prices relapsed in a stagnant market, the turnover being small and mostly professional, while trade reports were generally discouraging. Toward the end of the month there was more activity, due chiefly to the desire to liquidate holdings in face of enormous shipments of the metal from Atlantic ports. Three months' warrants changed hands at £57 17s. 6d. on April 28. Thereafter occurred a transitory recovery caused by covering of May prompts and strong advances on the New York Stock Exchange. The trade, however, remained unresponsive and values fell away, closing at £57 10s. for cash warrants, and £58 2s. 6d. for three months.

May started with a fall of 10s. per ton, caused mainly by unfavorable statistics; but at the end of two days the selling pressure had subsided and a recovery of 17s. 6d. was recorded, due to buoyancy in copper mining shares and influx of speculative orders. The next feature was a reduction in American prices, which weakened the London market and brought back prices to the starting point. Toward the

middle of the month a well sustained bull movement was initiated in Wall Street, which created great activity in stocks and broadened so as to attract speculators toward the metal. Brokers—undeterred by actual conditions of trade—encouraged their clients to invest for the rise, and a large volume of business resulted. The expanded demand was met by heavy selling, supposed to be for American account. Cash warrants advanced from £50 15s. on May 12 to £50 on May 19; the three months' price being maintained throughout at about 15s. premium. Meanwhile producers were alert to take advantage of the improvement, and accepted in many cases prices which were well below the Standard parity. Japanese brands being prominent after a long period of inactivity. The consumptive inquiry meanwhile was far from satisfactory, manufacturers being unanimous in bewailing the scarcity of orders. Prices gave way at the first sign of reaction in Wall Street, and gradually fell to £50 17s. 6d. at which cash warrants changed hands on May 27. Thereafter cheerfulness was imparted by the termination of labor troubles in the shipbuilding industry, and by reduction of the Bank rate of interest from 3 to $2\frac{1}{2}$ per cent, and the speculative movement again carried prices upward, the closing figures being £57 12s. 6d. for cash, and £58 5s. for three months. Manufacturers had meanwhile reduced their selling prices by £2 per ton, but without attracting much business thereby, and the general slackness of trade at home and abroad was very pronounced.

June was remarkable for the strength displayed by the market throughout the month in face of unfavorable statistics, poor trade, heavy offerings from Japan, unsettled and generally languid stock and share markets. There was sustained buying by speculative investors, who apparently regarded the future with confidence inspired by the improved industrial and political prospects in the United States. Leading producers were thus able to market their copper without conceding any substantial reductions in price, and were accordingly independent. The result was that fluctuations were very narrow; the three months' price ranging from £58 5s. at the opening, up to £50 5s. on June 11, and thereafter by easy stages down to £57 on June 29. The mid-monthly statistics were unfavorable and helped the decline. American sellers, after having sold fairly well early in the month, made some trifling concessions in price, but without attracting much business thereby. The disquieting feature was the steadily increasing stocks, not only in public warehouses, but also in the hands of producers; consumption meanwhile betraying a serious shrinkage, particularly in France and Germany. The support which the market received was, therefore, based more on sentiment than on sound eco-

nomic conditions. Closing prices were £50 15s. cash, and £57 7s. 6d. for three months.

In July, prospects at the opening were not encouraging, trade being restricted and demand readily met by dealers. Statistics disclosed an increase of 6553 tons during the previous month, and stocks in private hands were heavy. Further shipments of the metal from the United States and from Japan promised to be heavy, and consumers were naturally reluctant to buy more than they actually required. Early in the month, however, speculation received an impetus from Wall Street where much optimism was imparted by prospects of a good harvest and by indications of expanding trade. The leading American producers of copper had meanwhile stood firm and now began to find a better home demand, and the London market improved in consequence. Three months' warrants, which had opened at £57 2s. 6d. changed hands in considerable volume at £58 12s. 6d. on July 9. Thereafter for a week or more operations were restricted and prices fell back a few shillings, the home trade being slack, though some improvement was noticeable on the Continent. On July 20 occurred a sharp rise in shares, whereby general optimism was revived; the sentiment soon extending to commodities, in which copper figured largely. Consumers now bought freely after a long period of abstention, and an industrial revival was manifest, particularly in electrical branches. Producers, having sold largely, held firmly for advanced prices, and the Standard market was correspondingly strong. Three months' warrants changed hands on July 24 at £60, a figure which had long been regarded as a remote possibility, and from which a temporary relapse of 5s. was soon recovered. American manufacturers bought largely at $13\frac{1}{8}$ @ $13\frac{1}{4}$ c., apparently without satisfying their requirements even at the higher figure. The most noticeable feature in the Standard market was the absorbing power of the speculative demand, notwithstanding the poor support afforded by the home trade, which was adversely affected by the advanced prices. Bull accounts were freely liquidated, and bear selling assumed large proportions, while large quantities were marketed from Japan, Chile, China and European producers; but the speculative force absorbed all that was offered, and on the last day of the month £61 was paid for three months' warrants. This was the eve of the statutory holiday when the market would be closed for two days, and absentees would be numerous. The market closed amid diverse conjectures as to the immediate sequel, final quotations being £60 for cash warrants, and £60 15s. for three months.

In August when business was resumed the market displayed considerable buoyancy in spite of an increase of 4423 tons

in the visible supply during the previous month. Prominent operators readily took over all that was offered by holders who naturally regarded the situation as unsound, in view of increasing stocks and diminished trade. The latter was indeed evident throughout the month, for consumers found orders few and were reluctant to buy the metal until obliged. Finance, however, was powerfully employed in keeping up prices of metals and of mining shares, and the cheapness of money contributed thereto. The situation was virtually governed by the New York Stock Exchange, while trade languished. American consumers found it necessary to cover accumulated requirements, and their purchases relieved producers of all superfluous holdings; and successive advances raised the selling price of electrolytic to $13\frac{3}{4}$ c. Fluctuations on the London market were within narrow limits, the highest being touched on Aug. 10, when three months' warrants commanded £63, and the lowest on Aug. 25, when £60 7s. 6d. was accepted; and the month closed with a steady market, cash warrants at £61 2s. 6d., @ £61 5s., and three months at £61 17s. 6d.

In September the fortnightly statistics showed an increase of only 287 tons, which was generally regarded as favorable. Trade showed some signs of expansion, but the rising prices were checked by instability in the share markets. Consumptive inquiry mostly came from the Continent, where electrical enterprise was active, being chiefly manifest in the projected electrification of railways under the lead of the German government. Improved conditions in the iron and steel trades tended to inspire confidence, and prices rose until, on Sept. 8, up to £61 5s. was paid for cash warrants, and £62 5s. for three months. At this point the improvement was checked by the leading American producers unexpectedly reducing their price for electrolytic quality by £1 per ton. By the middle of the month recovery was in progress under the stimulus of buoyant share markets, but a relapse followed on the publication of statistics showing an increase of 3358 tons. American reports of trade and finance became less optimistic as the approaching presidential election engendered political excitement. Moreover it was known that production of the metal in the United States and in Mexico was now proceeding at full capacity and overtaking all previous records of output. By Sept. 22 prices of Standard had fallen to £50 2s. 6d. and £60 respectively. Thereafter the market improved for some days, but dealings were mostly professional and lacked trade support. The close was quiet, there being neither active demand nor eagerness to sell; cash warrants being held for £50 17s. 6d. and three months for £60 15s.

October found the market sensitive at

the outset, the continued increase in the visible supply inspiring caution. American consumers bought but sparingly pending the issue of the election, and the American producers found Europe their best outlet, particularly for electrolytic quality. In two days the London price dropped 12s. 6d. per ton. Grave political news followed, threatening war in south-eastern Europe, whereby the share markets were much disturbed; but the copper market withstood the shock remarkably well. The lowest was touched on Oct. 9, when cash warrants stood at £59 2s. 6d. and three months at £60. Thereafter confidence was restored as political complications subsided and the share markets became buoyant, and prices advanced rather sharply, only to relapse gradually almost to the previous level. Trade generally was very slack, the electrical industries affording the only exception, and the increasing output from the mines gave promise of abundant supply. On Oct. 21 a recovery set in, due primarily to increasing firmness in Wall Street, and the price of the metal advanced £2 in two days. Producers' firmness contributed to this more than immediate demand; but with an improving demand from India and increasing evidence of the early electrification of continental railways, sentiment rapidly favored the rise which thereafter was gradual but steady. Toward the end of the month there were persistent reports of a powerful syndicate operating in support of the market. The rumor was not visibly substantiated, but it coincided with successive advances in the American price of the metal and a general improvement in the European demand. The month closed with a firm market, in spite of heavy realizations of speculative holdings, and with sentiment distinctly optimistic. Closing values of Standard were £61 15s. for cash warrants, and £62 12s. 6d. for three months.

November opened quietly under shadow of the impending election in the United States. The result was known on Nov. 4, and was the signal for a moderate improvement in values in the London market where, by Nov. 9, cash warrants commanded £65 2s. 6d. per ton, and three months' £66 5s. New York prices advanced more rapidly and touched 14½¢. for Lake Superior brands, the consumptive inquiry being apparently unsatisfied even then. The speculative element was equally active, and was responsible for some reaction from the foregoing figures, particularly toward the middle of the month when profit-taking coincided with instability in the share markets. American prices of the metal also relapsed, but this was due to concessions made by dealers, producers having sold too largely to allow of any abatement of their prices. Offerings, however, were readily absorbed, and evidence of expanding trade were everywhere apparent. The lowest was touched on Nov. 23, when cash warrants changed

hands at £62 12s. 6d. and three months at £63 12s. 6d. At this level influential support was forthcoming, and carried values up to £64 2s. 6d. and £65 respectively on Nov. 25, after which values receded a few shillings, but with strong undertone due to improved trade purchases and general optimism in regard to the next year's prospects. Closing values were £63 17s. 6d. for cash warrants, and £64 15s. for three months.

December was clouded at the outset by sinister political developments, as also by instability in the stock and share markets, while the approaching holidays and cessation of work during stock-taking tended to further restrict the consumptive trade. There was considerable liquidation of holdings—chiefly by continental sellers—early in the month, and prices fell back in consequence; but the market showed great power of absorption and was at no time demoralized. The lowest was touched on Dec. 8, when £62 2s. 6d. was accepted for cash warrants, and £63 2s. 6d. for three months. Producers were firm in maintaining their prices, and American advices were generally encouraging, though dealers occasionally shaded their prices. Speculative enterprise raised London prices to £63 7s. 6d. cash, and £64 7s. 6d. for three months, on Dec. 10; but at this level sellers predominated and caused a gradual relapse during the next few days to the extent of £1 per ton. At this time vague rumors were heard of a projected combination of the leading American producers to regulate the price and otherwise to steady the market. Trade generally was slack, and manufacturers apathetic; but underlying conditions were considered hopeful and values were well maintained. The closing quotations were £63 15s. for cash Standard.

The London Lead Market in 1908

SPECIAL CORRESPONDENCE

January found metals generally in improved demand and a tendency toward higher prices. There was considerable covering of bear sales in lead, £14 15s. per ton being paid for forward delivery, and consumptive demand was brisk until checked by the higher figure. Thereafter a few selling orders sufficed to depress the prices down to £14 on Jan. 9, whereat buyers showed renewed interest, and a fair volume of business was recorded. About Jan. 20 large speculative purchases were made, coincidently with bull operations in certain mining shares; and the price was again carried up to £14 15s., but again not maintained thereat. A temporary relapse, however, was soon recovered in virtue of active business which gradually raised the price to £15 5s. This figure induced realizations, followed by

some easing of the price. Consumers' demand slackened, but with every indication of large requirements to be covered and stocks everywhere small. The closing prices were £14 17s. 6d. for foreign brands, and £15 2s. 6d. for English.

February found the London market active, but with few inquiries from provincial consumers, and these were readily met by cheap offers from America, and values receded accordingly until, on Feb. 12, spot parcels commanded only £14 2s. 6d. This figure attracted some speculative attention and a temporary rally of a few shillings. Heavy arrivals induced renewed depression, consumers holding aloof, and £13 13s. 9d. was accepted on Feb. 27. Thereat buyers showed more interest, and a fair volume of business took place at improving prices which, at the close, stood at £13 17s. 6d. for foreign brands, and £14 2s. 6d. for English.

In March, the tendency was rather strong at the opening, £14 3s. 9d. being paid for forward delivery; but prices receded on spot metal being pressed for sale. This touched £13 12s. 6d. on March 4, but thereafter holders were unwilling to sacrifice parcels at so low a level, and the price hardened to £14. Buyers, however, were intimidated by the plethora of prompt metal, and gave but meager support, whereby values were reduced by a few shillings until March 17, when a gradual recovery set in, prompted by the absorption of spot parcels and an influx of Russian orders. The improvement lasted until March 25, when £14 12s. 6d. was paid for forward delivery; but at this point speculative holdings were liquidated and support was lacking. Prices quickly receded to £14 5s. @ £14 7s. 6d. for foreign brands, and £14 7s. 6d. @ £14 10s. for English, at which figures the market remained uneventful for the rest of the month.

April showed a gradual and almost uninterrupted decline in values. Opening with foreign brands from £14 2s. 6d. @ £14 7s. 6d. the market was depressed by the forced sale of numerous arriving parcels, consumers' demand being meager and readily met by keen sellers. Only on April 28, after £13 had been accepted for prompt delivery, did an improvement set in, raising the price to £13 5s. for prompt delivery and £13 10s. for July and August, English brands being quoted £13 10s. @ £13 15s. The month closed thus with a rather improved demand.

May was uneventful, with narrow fluctuations and only moderate consumptive demand. The market opened rather easier at 13 2s. 6d. for foreign brands, and £13 7s. 6d. for English. It developed some little strength toward the middle of the month, chiefly for forward delivery; £13 7s. 6d. being paid for foreign brands deliverable in July. On May 21 a decline set in, prompted by pressure of early arrivals in a market unsupported by trade demand, until in one case £12 15s. was accepted. The closing days of the month witnessed

a slight improvement, final quotations being £12 17s. 6d. @ £13 2s. 6d. for foreign brands, and £13 2s. 6d. @ £13 7s. 6d. for English.

June opened very quietly, consumers being reluctant to buy in view of the approaching Whitsun holiday. Foreign brands opened at £13, and receded to £12 12s. 6d., then stiffened moderately, but with little business passing. It was not until June 29 that any activity was manifest, when forced realizations brought the price down to £12 6s. 3d. for prompt delivery, and £12 10s. for September. This level proved attractive to buyers, and a fair volume of business took place. Closing prices were £12 6s. 3d. for July foreign and up to £12 12s. 6d. for extended delivery, English brands being held for £12 12s. 6d. to £13, according to time of delivery.

July found the market ripe for moderate improvement, partly in sympathy with other metals, but more in consequence of reduced selling pressure. Consumptive inquiry was fair throughout, and the improving tendency was manifest in higher prices paid for forward delivery than for spot lots. Toward the close of the month activity was very general both in Europe and America. The result was a slow but persistent improvement of about 15s. per ton from the outset to the close; final values being £13 7s. 6d. for foreign brands, and £13 10s. for English.

August found supplies under strong control and not likely to be pressed for sale. The gradual improvement in values continued until £13 15s. was paid. On Aug. 11 the metal markets generally showed weakness, and lead was found vulnerable to the attacks of bears, while consumers judged well to hold aloof. A reduction of 5s. eventually brought out a fair volume of business, but prices gave way further as demand was satisfied. Fluctuations were at no time important, and the month closed with a quiet market; foreign brands being quoted £13 5s. @ £13 6s. 3d.; English £13 7s. 6d. @ £13 10s.

September was an uneventful month, prices fluctuating within very narrow limits. Business was restricted at the outset, but showed early signs of revival as manufacturers came forward to replenish their depleted stocks. Russian and other continental demand coincided with restricted supply and tended to keep the market firm. Prices hovered between £13 5s. and £13 1s. 3d. until the closing days of the month, when available supplies were insufficient to meet the demand, and inquiries were more frequent. Final values were £13 7s. 6d. for foreign brands, and £13 10s. for English.

October was uneventful on the whole, and fluctuations were narrow. English consumers bought moderately, and there was steady demand from Russia and other continental countries. Some scarcity of prompt supply raised the price to £13 15s.

early in the month, but the scarcity was soon relieved, and was followed by some depression consequent on political complications in southeastern Europe. The lowest touched for foreign brands was £13 5s. Later in the month prices stiffened on the news of labor trouble threatened at the Broken Hill mines; and with help of speculative buying, values rose to £13 10s. for foreign brands and £13 12s. 6d. for English, whereat the month closed.

November opened with a strong market, particularly as regards forward delivery. Speculative interest was aroused, and was further stimulated by rumor of increasing labor troubles at the Broken Hill mines. Up to £14 5s. was paid on Nov. 11 for forward delivery. Consumptive inquiry, however, was disappointing, its shrinking being largely due to slackness in the building trades. Later in the month prices were depressed by heavy arrivals in excess of requirements, and by adverse speculative operations. Confidence in the early revival of trade in the building and electrical industries helped to maintain relatively high prices for forward delivery; but the general trend was downward, and closing prices were £13 2s. 6d. @ £13 5s. for foreign brands, and £13 5s. @ £13 7s. 6d. for English lead.

December opened with a depressed market consequent on heavy arrivals of the metal which at one time commanded no more than £13 2s. 6d. Thereat, and at a few shillings more, bears covered their sales, consumers bought moderately, and producers became independent. An improvement of 5s. per ton ensued, but was of short duration, the slack season tending to weaken a market only poorly supported. The undertone, however, was fairly good owing to the prevailing optimism regarding trade for the ensuing year. The closing price was £13 for foreign and £13 2s. 6d. for English lead.

The "Step Process" for Treating Iron Ores

From time to time articles have appeared in local papers with regard to a new process for treating iron ore devised by John T. Jones, of Iron Mountain, Mich., which was to "revolutionize" the iron and steel business. These articles, however, contained no definite information as to its exact nature. For the first critical and authoritative description of the process, which possesses considerable interest, we are indebted to the *Iron Trade Review*, of Cleveland, Ohio. It is known as the "step process," though the inventor calls it the "Ardis furnace."

THE STEP PROCESS

Up to this time, all of the operations of the furnace have been purely experimental both as regards the mechanical

and chemical problems to be worked out. These experiments have not involved the principles upon which the process is based, but have had to do with the regulation of temperatures, speeds and gearing, and the character and operation of the gas producer. Now it is claimed that a sufficient tonnage of ore has been successfully put through the furnace to establish the correctness of the principles involved, the economy and practicability of the process and the rate at which the product may be shipped.

The plant comprises principally a horizontal rotating furnace and a gas producer. The process consists of the reduction of the metallic oxides of any ores to the metal and applies, therefore, to copper or zinc oxides as well as iron. As applied to iron ore, for the reduction of which this furnace was particularly designed, the process yields a product which may either be charged into an ordinary "balling" furnace and thence to the familiar squeezing rolls and blooming mill to be made into muck bar, or it may be put into the open-hearth furnace, in place of scrap, to be manufactured into steel. The plant now erected and the operations so far carried out have to do only with the metallizing of the iron oxide. Beyond this step the operations are not new and have been successfully conducted for a long time. In the future of the project, it is expected to introduce at this plant the other operations and ship, from the immediate vicinity of the ore mines, only the finished product. The commercial success of the undertaking, therefore, carries with it, if it materializes, very great possibilities.

THE FURNACE

The furnace consists of a steel tube 8 ft. in diameter and 120 ft. long, lined with firebrick and very similar to the ordinary cement kiln. It is mounted almost horizontally with a slight inclination toward the discharge end to aid in the movement of the ores. The tube is equipped with two bearing rings and is supported on rollers mounted on concrete piers. A spur-gear ring encircles it by means of which and a train of gears driven from an electric motor, the furnace is rotated at the rate of one revolution a minute. The ore is brought in on a railroad track which parallels the furnace and is dumped from hopper-bottom cars into the boot of an elevator which raises the ore into a headframe at one end of the furnace. Here it is discharged into a rotating screen with a ¼-in. mesh. That which passes the screen is ready for charging into the furnace and the lumps are carried up to a crusher which breaks them down to the same size. The ore thus prepared is charged into the kiln.

THE GAS PRODUCER

At the other end of the furnace the gas

producer is erected. This is an ordinary water-sealed gas producer using any kind of bituminous coal and evolving a rich hydrocarbon gas. This gas is admitted into the end of the kiln in excess. Air is admitted through a slip ring or bustle-pipe which encircles the kiln close to this end. The mixture results in a combustion which produces the necessary heat in the kiln and the excess hydrocarbons reduce the oxide in the ore. The reactions are similar to those in the upper zones of the blast furnace except that the source of the carbon is different and, in the experiments so far, the temperatures have been about the same. It is understood, however, that some developments have operated to suggest a change in the temperature at which this reduction can be brought about. The operation in this furnace does not go far enough to carburize the metal and the product is practically as free from carbon as was the ore.

THE PRODUCT

The product in appearance is similar to some specimens of sintered blast-furnace dust. It is hard and porous and when worked with a file shows clearly the metallic character of the sponge iron. In the product the metal is intimately associated with the gangue of the ore, largely silica. This is not affected by the process, but it has been found consistently that the phosphorus content is reduced in the operation. No explanation of this phenomenon is attempted. While sulphur is not at all troublesome in Lake Superior ores, it could be easily roasted out at the temperatures under which the kiln operates. The ore that has been used came from the Mitchell mine on the Marquette range. This is a high-grade ore and the silica content of such ore would have but little importance whether the product were used for making iron or steel. One of the possibilities which this process is expected to develop, however, is the use of low-grade, high-silica ores. This kind of ore, running in the neighborhood of 40 per cent. in iron and 30 per cent. in silica, abounds in the immediate vicinity of Iron Mountain and Antoine, where the furnace is located, and a large percentage of the ores of the eastern end of the Menominee range are of like character. The promoters of this furnace have secured an interest in the ores of the Randville district, a high-silica territory only a few miles from Iron Mountain, so that the freight on the ore delivered at the furnace should be not over half of the rate now charged for hauling from the mines to Escanaba. The crushing of the ore also for this furnace is no more than has to be done with a number of the ores from this district now, in shipping for blast furnace use.

With a large percentage of silica in the ore, however, there will be a corresponding percentage of this furnace product to

be slagged off in the balling furnace. This will undoubtedly carry off some iron with it, just how much is a question, although this trouble would seem quite possible of remedy. Where the product is to be used for charging into open-hearth furnaces, the silica will be most objectionable and the added cost of treatment either by a compound acid-basic operation or otherwise is problematical.

GENERAL CONCLUSIONS

No general comparative statement of costs can be given at the present stage of operation. It is claimed by the inventor that it is possible to turn out the product at a cost of not more than \$1.50 per ton. If this estimate is reliable, and if the product of the furnace can take the place in the manufacture of muck bar and steel that is claimed for it, it is apparent that even at plants far removed from Iron Mountain, pig iron and scrap, respectively, can easily be supplanted in these processes.

In brief, the claims made by the inventor are that the furnace will obviate the need of steel-making pig iron and the blast furnace producing it. It will render unnecessary the decarburizing portions of all steel-making processes and, most important, it will result in the restoration of wrought iron to common use. It is hardly necessary to add that much further work on a commercial scale is necessary before these claims can be fully accepted.

J. C. Buckbee & Co., Chicago, are the constructing engineers for the plant; the furnace, crusher and driving motors were built by the Allis-Chalmers Company. Current for driving the motors, which are five in number and respectively 75, 40, 30 and 5 in size, is supplied by the Iron Mountain Electric Company.

Railroad Rates on Iron and Steel

SPECIAL CORRESPONDENCE

A complaint filed with the Interstate Commerce Commission by the Babcock & Wilcox Company against the Atchison, Topeka & Santa Fé railroad, the New York Central & Hudson River, the Lake Shore & Michigan Southern, the Pennsylvania and the Central Railroad of New Jersey raises some points regarding the transportation of iron and steel products which are likely to be of considerable significance when a decision has been rendered. The complainant is a corporation with works at Bayonne, N. J., while the rates complained of are those affecting transcontinental traffic and specifically shipments to Redondo, Cal. The schedule as published by the Atchison, Topeka & Santa Fé in a joint tariff designated by the commission as No. 375, and by the road as 5970, shows rates from New York, Boston, and common points (of which Bayonne is one) including the following

provisions: "Boiler heads or ends, flanged, minimum carload 30,000 lb., \$1.10 per 100 lb. Castings N. O. S. plain, as from sand, in no way hand or machine-finished except being drilled with bolt holes O. R. B. minimum carload 30,000 lb., 85c. per 100 lb. Articles of iron or steel O. R. wet or rust angles, channel beams, columns and girders, minimum carload 30,000 lb., 85c. per 100 lb." Prepaid shipments having been made from Bayonne to Redondo under these provisions the roads concerned declined to give up the goods at the California terminal unless additional freight under the same rating as that for boilers was paid. The assigned reason was that the boiler heads, rough castings, etc., shipped were ultimately intended for the construction of boilers and hence should take the rate published for boilers. Further, the roads declined to accept further shipments under this tariff for the same reason. The complainants ask for an order requiring the roads to accept rough iron and steel products at the published rate independent of their ultimate use.

Dredge Mining and Hydraulic Sluicing in Victoria

D. B. Sellars, the engineer in charge, reports (*Monthly Mining Report*, June 28, 1908) that the number of gold-dredging and hydraulic sluicing leases in force in Victoria on Dec. 31, 1907, was 323, the systems in use being: Bucket, 45; hydraulic pump sluice, 84, and jet elevator, 4.

One pump-sluice plant dealt with 12,200 cu.yd. of material in a week and five others from 10,000 to 11,000 each. The depth of ground worked varied from 6 to 62 feet. Forty-five bucket dredges in 1599 weeks raised 10,371,852 cu.yd. of material yielding 41,085 oz. gold. Eighty-four pump hydraulic sluices in 2092½ weeks dealt with 9,670,362 cu.yd. of over-burden and wash-dirt, yielding 55,272 oz. gold. Four hydraulic jet elevators in 76 weeks put through 157,678 cu.yd. of alluvium for a return of 1464 oz. gold. The total area worked by these 133 plants was 739 acres, the average yield 132.3 oz. gold per acre, and the number of men employed 2468.

Six plants using hydraulic sluicing by gravitation in 86 weeks handled 396,116 cu.yd., yielding 2394½ oz. gold. The total quantity of material treated during the year by dredge and hydraulic sluice mining by gravitation was 20,596,008 cu.yd., the gold obtained being 100,216 ounces. This branch of the mining industry shows an increase of 12,550 oz. as compared with the previous year.

Concluding, Mr. Sellars says that the introduction of some cheap, rapid, non-injurious and efficacious precipitants for the clarification of sludgy water would be of great benefit.

The Virginia & Mexico Cyanide Plant

By MARK R. LAME*

The Virginia & Mexico Mining and Smelting Company, under its general manager, Jesse Scobey, is building a modern cyanide plant at Hostotipaquillo, State of Jalisco. Mr. Scobey has had an extended experience in the States and in Mexico, and has brought together a plant combining the best features of accepted practice. The plant is being built in a mill formerly occupied by a lixiviating

Federal Government has declined to extend the time for completion of the railroad, work is being crowded in order to complete the road within the time limit.

The machinery for the Virginia & Mexico company was shipped by steamer from the United States to Tampico, and thence by rail to Etzatlan. From here it is packed on mules over the mountains to Hostotipaquillo. All this machinery is now at Etzatlan, on the trail, or at the mill, so the initiation of the plant will not now be long delayed.

The ore, after careful sorting, will be crushed in Blake breakers and fed to 30 stamps, crushing in solution. Wilfleys

usually overlooked. Emergency sumps are provided for accidental overflows. These occur in the best regulated mills, and wilfully ignoring the inevitable, usually result in the monthly loss of more than the cost of the necessary extra tanks and pumps with cement floors and drains. No plant milling in solution should be built without a complete system of such floors and drains.

The usual difficulties of mill construction are more than doubled by the difficulties of getting sectionalized machinery such as is required in this mill, followed by the difficulties of getting prompt transportation. An inquiry for delivery on a

WILFLEY TABLES ON BURRO BACK

PEONS PACKING IN MACHINERY

STAMP MILL AND CYANIDE PLANT, VIRGINIA & MEXICO MINING AND SMELTING COMPANY

plant, which is so large that most of the cyanide equipment will be under cover. The question of power is still an open one in the district, though reports appear with great regularity that power from Lake Chapala will be distributed over the entire State. The Oedro Analeco power proposition contains possibilities of power for this entire district, and as the dam is already built this seems to be the probable solution of the question.

The extension of the Southern Pacific from the coast to Guadaluajara will greatly help this section of Mexico, and as the

will remove coarse concentrates. The tails from these will go through dewatering cones to two 16-ft. tube mills and then to a second set of Wilfleys for further concentration of the fine sand. Sand collectors with Butters-Mean distributors take the tailings from the second bank of concentrators, sending the slime to storage and air-agitation tanks, and the sand in cars to the leaching tanks. Slime will be washed in a vacuum filter of ample capacity, and solutions precipitated on zinc shavings, the bullion being melted rather than shipped as precipitate. One feature in the mill is given consideration which is

sectionalized pump will bring a reply from the manufacturer asking if the base, weighing 1200 lb., is too heavy for one piece. I wonder what kind of mules they think grow in Mexico?

In the illustrations two methods of transporting machinery in this district are shown.

The output of copper ore in the United Kingdom in 1907 was 6792 long tons, against 7758 tons in 1906. In 1893 the production of ore and precipitate was about 210,000 tons, valued at more than £1,000,000.

*Mining engineer, Mexico City, Mexico.

Mining Legislation in Congress

SPECIAL CORRESPONDENCE

Several bills have been introduced in Congress at the present session, which affect mining interests. Among these the following are noted:

REGULATING HYDRAULIC MINING

A bill (H. R. 25,547) relating to the regulation of hydraulic mining by the California Débris Commission has been introduced by Representative Englebright and referred to the committee on Mines and Mining. The bill provides that the California Débris Commission (created under the act of Congress of 1893) shall make an estimate of the number of cubic yards of mining débris or solid material that will eventually be carried into the navigable rivers or streams of California either through the operation of a given mine itself, or by escaping from the impounding basin appertaining to the mine. The commission shall then, under rules and regulations to be approved by the Secretary of War, provide for the issuing of a license or permit for the working of the mines and for the removal of the débris or an equal amount of solid material by those who are responsible for its being disturbed from the original places of deposit. The commission may, however, instead require the payment to it by the mineowner of the net cost of removing such solid material from the navigable streams; and the commission is to be empowered to expend all moneys received in this way from mineowners in dredging and improving the navigable streams affected, or their tributaries. In the event that the mineowners elect to remove the débris themselves, the commission may indicate to them the point or points at which the removal shall be made. The license for the removal of solid material from navigable rivers may be issued directly by the commission to those who already have licenses to mine by hydraulic process; but in the case of future applications for licenses the issue shall take place only in accordance with the new regulations to be made up and approved by the Secretary of War.

SURVEYS OF MINERAL LANDS

The following bill (H. R. 25,396) for the relief of applicants for mineral surveys has been introduced by Representative Needham of California:

"That the Secretary of the Treasury be, and he is hereby, authorized and directed to pay, out of the moneys covered into the Treasury from deposits made by individuals to cover cost of work performed and to be performed in the offices of the United States surveyors-general in connection with the survey of mineral lands, any excess in the amount deposited over and above the actual cost of the work per-

formed, including all expenses incident thereto for which the deposits were severally made. Such repayments shall be made to the person or persons who made the several deposits, or to his or their legal representatives, after the completion or abandonment of the work for which the deposits were made, and upon an account certified by the surveyor-general of the district in which the mineral land surveyed, or sought to be surveyed is situated and approved by the Commissioner of the General Land Office."

The Lick Branch Explosion

At 8:30 on the morning of Jan. 12, a second explosion occurred at the Lick Branch mine, of the Pocahontas Consolidated Collieries Company, in southern West Virginia. It will be remembered that 51 men lost their lives in this mine on Dec. 28. In this latest disaster, it is believed that 105 miners have perished.

All of the bodies so far recovered were badly burned and identification of the men has been made by means of effects upon their persons. The force of the explosion shook houses for half a mile around and windows were blown out of many buildings.

Mine Foreman Bowers, who was near the entrance, was blown from his feet by the explosion, but managed to crawl out safely, as did also Robert Smith, a miner. The main entry of the mine is four miles long, running from one side of the mountain to the other. Débris was blown from both entrances, which gives an idea of the tremendous force of the explosion. The fans which furnish ventilation for the workings, as in the former explosion, were not disabled, and are forcing fresh air into the mines.

A train was rushed from Bluefield to the scene of the disaster, carrying brattice and other material to be used in the work of exploration and rescue. The debris from the explosion of two weeks ago had not been cleared away and twenty men were engaged in this work. Nineteen contract miners with their crews were at work in a new entry, and it is feared that all of these men were lost.

The majority of the miners employed in the workings were Americans. The last body of the 51 victims caught in the December explosion was brought to the surface only last Friday, Jan. 8.

According to *Le Génie Civil*, Oct. 10, 1908, a mixture of kaolin and less than 80 per cent. chromite is more fusible than pure kaolin. To obtain maximum refractoriness, the mixture should contain not more than 10 to 15 per cent. of the clay. The fusion point of a mixture containing about the amount of clay is said to be higher than that of platinum.

Joseph Wharton

Joseph Wharton, the largest individual iron manufacturer in the country and a man of varied experience and attainments, died at his home at Branchtown, near Philadelphia, Jan. 11, aged 83 years. He was born in Philadelphia in 1826; entered business as clerk in a mercantile house in 1845; afterward engaged in the manufacture of white lead, and in 1853 organized the Lehigh Zinc Company, for which, in 1860, he built the first successful spelter works in the United States. In 1873 he bought the Gap nickel mines in Lancaster county, Penn., and then established at Camden, N. J., the first successful nickel and cobalt works in the United States. He then entered the Bethlehem Iron Company, subsequently the Bethlehem Steel Works, founding there the first armor plant in the United States. He retired from this company when it was reorganized. Meantime he had become largely interested in iron mines and blast furnaces in New Jersey, acquiring the iron deposits at Hibernia, Andover and Wharton. He had three blast furnaces at Wharton and Philippsburg, with a capacity of 600 tons a day. He also bought and operated coal mines in Indiana county, Penn. His activities, which continued almost to the day of his death, were many and various. He was for 12 years president of the American Iron and Steel Association. He was also a large owner and active director of the Lehigh Valley railroad until a year ago, when he retired. He was a director of the Farmers and Mechanics' National Bank and had also been a director of the International Nickel Company, which absorbed his nickel properties. In addition he was a frequent writer on industrial and scientific topics, and took a deep interest in education. Some years ago he founded the Wharton School of Finance and Commerce of the University of Pennsylvania, which he endowed with \$500,000. He leaves a fortune estimated at \$25,000,000, chiefly invested in lands and industrial enterprises. He always conducted his business as an individual, but in 1907, as a provision for the future, he organized the Wharton Iron Company, to hold his iron properties.

Small air hoists mounted on a bar are used in some of the mines at Mount Morgan, New South Wales, Australia. These are easily put up, the bar being placed vertically, and are used instead of a windlass in sinking winzes. These hoists are simple in construction, are light and can be moved easily.

In order to obtain the best results in an upcast shaft all crosscuts above the levels being worked should be blocked off in order that cool air may be prevented from entering the upcast shaft and so decreasing the natural ventilation.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, PRES. AND TREAS. ROBERT MCKEAN, SEC'Y.
505 Pearl St., New York.
London Office: 6 Bonnerie Street, London, E. C. Eng.
CABLE ADDRESS: "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for December, 1908, was 42,500 copies.

January 2.....	10,000
January 9.....	14,000
January 16.....	10,000

None sent free regularly, no back numbers.

The Situation in Copper

Ever since the development of the Bingham and Ely mines was begun we have been talking about the great increase in copper production to come from those places. The débâcle in the winter of 1907-08 diverted attention from what was impending and consequently the great increase in production in 1908 that we reported last week, which occurred in the face of what is called a "low price" for copper burst upon most persons as a surprise. There are indeed surprising features in the statistics, chief of which is the failure of a 13½c. average to restrict more severely the output of the small mines, whose aggregate made a handsome total in 1907. Alaska, Idaho and New Mexico did, in fact, suffer in 1908, but Wyoming, Missouri and Virginia held their own, while Colorado made a respectable increase. Vermont receded, but only temporarily pending the beginning of smelting by the Vermont Copper Company. Many of the small mines are, therefore, still able to live. This being so, the increases in the big camps were all clear gain.

In Arizona—Bisbee, Globe, Clifton and Jerome made increases, in some cases very large ones. At Butte, in spite of the shutdown in January and February, there was a gain of 29,000,000 lb. The great expansion of operations by the Mammoth swelled the output of California. The enlarged output of Nevada is, of course, explained by Steptoe Valley. The extension of the Garfield works in Utah made good the deduction of the United States, Bingham and Highland Boy smelters, and the Utah, Boston Consolidated and Utah Consolidated mining companies glutted it with ore. Indeed, the production of the mines in 1908 was doubtless larger than the production of the smelters, many of our reports showing much more copper received in ore than turned out as blister.

During the first part of 1908, Anaconda, Cananea, and three of the works at Salt Lake were idle. At that time production was below the rate of 1907. Anaconda resumed in March, and Cananea in the second half of the year. In the second half the Ely copper began to appear, and the porphyry mines of Bingham put additional capacity into operation. The Arizona districts and Lake Superior produced steadily right along. Lake Su-

perior made about the same output as in 1907.

It is doubtful as to the refineries, which are at least two months behind the smelters with respect to delivery of the finished product. In the early part of 1908 the refineries were operating at reduced capacity. They did not attain full capacity until after the blister copper of Washoe, Steptoe and Cananea began to reach them. This implies a smaller production from the refineries than from the smelters and it is probable that the refinery production of 1908 was less than the refinery production of 1907.

For the reason that we are not yet in possession of the refinery statistics, it is impossible to determine what the deliveries for domestic consumption and the unsold stock at the end of the year amounted to. The exports were large—about 664,000,000 lb., against 509,000,000 in 1907. The deliveries for domestic consumption are thought to have been upward of 400,000,000 lb. (against 539,000,000 in 1907, and 668,600,000 in 1906), but how much above that figure there are not yet data to show. At the beginning of 1908 there was about 120,000,000 lb. of refined copper in stock at the American refineries. At the mid-year the stock was believed to be fully as large. Some large sales were made in the second part of the year, but the present production of North America necessitates the disposal of nearly 4,000,000 lb. of copper on every business day on the average. It is well known that much of the copper exported has gone into stock abroad, where the visible supply is the largest for many years. There can be no doubt also as to the existence of an unsold stock on this side, but whether larger or smaller than at the beginning of the year cannot be safely pronounced. The visible stock in Europe at the end of 1908 was 124,723,200 pounds.

Yet the stocks on both sides of the Atlantic are of no such magnitude as to cause concern, if only consumption would regain its normal rate. The world's production of copper is now upward of 720,000 metric tons per annum. Assuming the consumption to be equal to the production, which is the case in the long run, about 60,000 tons per month are required. Consequently, the present stocks in Europe and America are only about two months' supply. It is misleading to compare present stocks with those of 10 or 20 years

ago when consumption was much smaller. In those former times it was recognized that two months' supply for the world was no more than is normally required as a safety reserve; if stocks were to be absolutely depleted, we should see such runaway markets, with their inevitable mischief, as we had in 1906-07.

It is the recognition of the soundness of this reasoning, together with their confidence in the march of business revival and the easy money market that has lately made producers act so stiffly, most of them being in a comfortable position. Although they have had at times to whistle to keep up their courage, they feel that they have successfully steered their craft amid reefs, shallows and breakers, and are now in comparatively smooth water. After all, 1908 was not a bad year, except to the wildcatters and the owners of so-called mines that are mines only when copper fetches 18 or 20c. The average price for copper in 1908—about 13¼c. is nearly 2½c. below the average of 1898-1907, but that decennial average is inflated by the extraordinary prices of 1906-07. If the latter years be excluded, the average for 1908 is only a trifle lower than the previous decennial average. A large proportion of the copper of North America is produced at a cost of 10c. and under, meaning the real cost which includes all development, depreciation and maintenance charges.

As to the prospects for the near future: Production is now going on at the largest rate in the history of North America and it is increasing every day. This is largely a matter of smelting capacity. Nearly all of the new works begun in 1906-07 have now been completed, but some have not yet gone into operation. Steptoe and Cananea are just beginning to get their full gait; also Bully Hill and Balaklala. Teziutlan is to start in February. The Imperial works released smelting capacity at Douglas. Humboldt did not operate in 1908, but is likely to do so this year; also the works of the United States Smelting Company near Salt Lake. The installation of converters at Yampa in 1908 added to the capacity of Utah, which will be further increased in 1910 by the Tooele plant. It does not seem as if there would be any scarcity of copper. Given an increasing production the market will be determined by the needs of the consumers. Business is undoubtedly improving, but

still very slowly. Some conditions lead to the belief that the revival in 1909 will not be so extensive as has been anticipated by the optimistic. It would not be surprising if the course of the copper market in 1909 should be on somewhat the same lines as in 1908.

Expert Advice

We have received a letter upon which we may base a word of advice, although in substance we have given the same many times previously. The letter is as follows:

"Will you please inform me where I can obtain some advice respecting an investment in a new gold mine in the * * * district of Colorado. I cannot afford to pay very much, because my investment will be only a small one in any case, but I cannot afford to lose my principal, and I should like to obtain some sound advice at a small cost. The mine is not a speculative offering (i.e., it does not figure in the stock market) but is owned by a few friends of mine who have excellent expert reports upon it and expect great things from it. It seems to me to be a good investment, but as I said in the first place, I feel that I ought to have advice of my own before risking my principal."

Our correspondent displays an intelligent recognition that mining is a business of which he is ignorant, and while offering attractions for investment, he ought to have professional advice. If every investor were so thoughtful and careful, the days of the wildcat promoter and the enthusiastic ignoramus and the visionary amateur would soon be numbered. The question is how can the small investor obtain good professional advice, the services of a competent engineer being necessarily costly? This difficulty is met ordinarily by the responsible banking houses, which are able to pay for the proper professional advice and pass it on to their clients with their own indorsement. In this way the banking houses which make a specialty of mining investments perform a valuable service. Their work is promotion in the highest sense of the term, and the profit which they realize is well earned. In all respects they are important and valuable members of the business community. The investor must, of course, learn to distinguish between the substantial houses of this class and the pinchbeck concerns which ape them.

However, these operations fall far short

of covering the ground. There are many cases, in all respects legitimate and praiseworthy, like that which is mentioned by our correspondent. To him, and others in a similar predicament, we can offer only these suggestions: Employ an engineer resident near the mine in question, who can examine it at less expenditure of time and money for traveling than one who would have to go out from Chicago or New York. Let two or more prospective investors club together to pay the bill. Take care to obtain a reliable recommendation as to the local engineer. If necessary, pay some other engineer, known personally or by reputation, for such a recommendation. Proceed, in brief, in very much the same way as if it were a matter of securing legal assistance to be rendered in a remote place.

The Verdict on the Marianna Explosion

Under present conditions it is hopeless to expect any beneficial result from the investigations of coal-mine explosions by the coroner and his jury. The questions asked of the witnesses at the inquest are usually of such a nature and so framed that no one will be embarrassed. Any evidence that is likely to incriminate the mine officials, or place the responsibility upon the living, is either concealed or carefully avoided.

We do not question the truth of the statement that in the majority of instances the miners themselves are to blame, and that with their lives they pay the price of such carelessness; however, in many cases, the mining company is directly to blame, and in almost all instances the mine officials are responsible for the accidents because they have permitted their employees to violate rules and mine coal in a reckless manner. If the miner who is guilty of disobedience were alone to pay the price for his negligence, the question would not be so serious; however, in all cases, the innocent suffer with the guilty.

No mining official can cleanse his soul from the stains of censure simply because the coroner's jury renders a verdict, stating that disregard of rules on the part of some miner was responsible for the lives lost. It is not enough to formulate rules and ask that they be obeyed; it is the duty of those in authority to see that they are obeyed.

The Marianna mine, as we have before stated, was designed to become a model operation. The plan of the workings as originally mapped out for guidance in the development work, was as nearly ideal as present knowledge of conditions in the Pittsburg field permits. Excellent rules were established, and the precautionary measures were of the best.

The coroner's jury brought out the following facts: 1. The mine contained gas. President Jones stated that about 2 per cent. was the maximum amount found in the workings at any time after the fan was installed. 2. Official instructions had been issued requiring that the miners use only fulminate powder in putting off shots. This rule was later modified and miners were permitted to use carbonite powder in places where the holes were wet. The use of black powder had been absolutely forbidden. 3. After the explosion, it was found that some of the miners had been using black powder, and a can of this explosive was found in one of the entries. 4. The dust was sprinkled down before shots were fired at the working faces. 5. The fan's indicator card showed that the fan stopped at 10:30. 6. Mixed lights were used in the mine. 7. It was found that there had been instances of gross violation of the rules, and recklessness on the part of the miners. 8. In some instances coal dust had been used in tamping. A cart-ridge to be used in tamping was found filled with slack and dust. 9. The explosion occurred at 10:54 in the morning.

The above statements of fact comprise the important evidence submitted at the inquest. The jury which sat on the case was composed of five farmers and one machinist. The verdict of these worthies was that the explosion was due to a blown-out shot in Blanche entry No. 3, which ignited the gas and dust, and that a secondary explosion occurred in the main dip entry almost simultaneously.

It seems unnecessary to comment on the evidence. Every experienced miner knows that in a gaseous mine, where mixed lights are used and the holes are charged with black powder, having coal dust for tamping, an explosion may happen. It might have occurred even to a jury of farmers to ask why the fan stopped at 10:30 if the explosion took place at 10:54. However, such a question would only have delayed proceedings and might have been considered impertinent. The recent inquests to investigate mine disasters discredit the

law; not the intelligence of the jurors, who are apparently selected for the absence of intelligence. Incidentally it may be remarked that Henry Louttit, inspector for the district, who was at the Marianna mine when the explosion occurred, has resigned his position.

Gold Production in the Transvaal

The cabled reports from the Transvaal indicate that the December report of production was swelled even to a greater extent than usual by the inclusion of miscellaneous amounts of gold, and of reserve gold by those companies which adhere to the reserve system. The total reported for the month was 660,600 oz. fine gold, which exceeds the November output by 46,229 oz., and is much greater than that for any other month in 1908. This large report brings the total for the year up to 7,054,574 oz., or \$145,818,045 in value; an amount \$318,000 greater than we estimated in the annual review. This is the greatest production ever made in a single country, and is greater than the entire production of the world only 17 years ago, in 1891 and for many years previous to that. In round figures, the Transvaal produced a little over one-third of the world's total for last year.

The causes for the increase over 1907, which was \$12,466,000, were fully explained in the article on the Transvaal in the JOURNAL of Jan. 9. It does not appear that the climax of production has yet been reached, but it is hardly possible that as great gains can be recorded in the coming year as the last three years have shown in South Africa.

The Conservation of Mineral Resources

The first practical fruit of the recent report of the Conservation Commission was the withdrawal from entry, by executive order, of the public lands containing phosphate rock in certain western States, and all the public lands in the petroleum and natural-gas field in northwestern Louisiana, known as the Caddo oil field. Previous to the conference of the governors last May, the public coal lands in the western States had been withdrawn. This is proper action. It is to be regretted that

the scope of the Government in this direction is so limited. But, although the President, with the advice of the Conservation Commission, will probably be unable to accomplish much directly in the way of preserving our natural resources, an immense stride has been achieved through the awakening of public sentiment to the necessity for reducing the waste of resources that cannot be replaced. We venture to predict that the historian of the future will pronounce this to be one of the greatest events of the present administration.

Conditions of Gold Production

The great production of gold in the United States in the year 1908 and the reason for it, are in considerable part due to the increased proportion of operations conducted on a large scale. While the prospector and small operator still survive and their influence is not to be neglected, the production of gold is year by year coming to be the result of corporate work and the use of capital, rather than of individual effort as it was in the days of early placer mining in California and the Rocky Mountain States; and even up to the time of the first rush of discovery in Alaska. One result of this is that gold mining is yearly becoming more systematized, and that the place of the individual is becoming smaller and less important. In other words gold mining has shared in the general concentration of industry; though this process has been slower, owing to the peculiar conditions affecting the discovery and mining of the standard metal.

THE FIRST week of 1909 brings with it the obituary notices of an unusual number of prominent men. Among these are James Corrigan, one of the pioneer shippers of ore from the Lake Superior country, and a large owner of iron mines and furnace property; Joseph Wharton, the oldest and largest independent iron-master in the East, and a man of many activities, who had made his mark in nickel and zinc as well as in iron; and Herman Justi, a close student of labor questions, an able writer on them, and a successful adjuster of many labor troubles in the western coal trade.

Comments on Questions Arising in Technical Practice and
Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Mining Safety Laws

The JOURNAL published, Dec. 5, a digest of State statutes relating to safety in metalliferous mines. The names were there recited of certain States that possess such acts applicable to coal mining only. Eleven States were also enumerated as having no mining safety laws at all. They include five New England States, two Southern and four Western States, the last group consisting of California, Washington, South Dakota and Kansas, all prominent mining regions.

Suspicion was aroused that this curious deficiency might be due to the fallibility of the source of information from which the syllabus was compiled. It is not to be presumed that letters received on request from mine inspectors and similar officials will be conclusive as to the laws standing on the statute books of their States. Those laws, however, are readily and perfectly ascertainable by reference to the books themselves. In most, if not all of our States, the statutes up to a recent year have been codified or compiled and so well indeed that the entire body of mining legislation may be found in a moment. Any subsequent enactments may be ascertained with almost equal facility by a glance at the volumes of session laws.

Recourse to the statute books has proved the defectiveness of those informal statements. Setting aside the New England States, and Virginia and Louisiana, it appears that all of the four Western States named possess more or less statute law on mining safety. California has a little. South Dakota has considerable, especially relating to the office and duties of the inspector of mines. Washington and Kansas have rather copious colliery codes, together with some legislation pertinent to metalliferous mines. A resumé of the acts in force in these States is presented herewith.

COMMON LAW ALSO APPLIES

Statute law does not, however, comprise all that governs mining safety. Through the application of common law principles, by the courts, to cases of alleged negligence that are constantly arising, there has grown up a great body of definitions of the precautions that a reasonable mine owner must take, which rules have the force of law quite as much, though not quite in the same way, as if enacted by a legislature. Thus there are many cases on hoisting signals, machinery guards, tamping dynamite, etc., referring

either to mines or to other work in which the same principles are involved.

Statute law is often a mere declaration of the common law. Legislatures formally enact those rules that have already been established by court decisions. Thus, an examination of judicial opinions is important in determining what precautions for safety are recognized as necessary and proper.

It is understood, however, that the purpose of the committee's present legislative recommendations is not a mere codification of the common law, but is to be distinctly in advance thereof. That is to say, the committee proposes to lay upon mine operators duties dictated by the views of a growing enlightenment, and will not rest content with the minimum of precaution under which, on traditional principles, a mine owner can escape damages for culpable negligence.

Further, it may be suggested that the mining inspectors of the States must have established many subsidiary rules and practices which, though not standing upon the statute books have virtually the force of law.

SOUTH DAKOTA

The Political Code, revised 1903, contains a chapter on "Mines and Mining" (Chap. 24, Secs. 2532-2586). In Article 6, "Miscellaneous Provisions," is found some legislation on safety in mines. There is also a chapter on the office and duties of an inspector of mines. Subsequent to the above codification, laws have been enacted relating to ladderways and bell signals.

It would appear that, while the statutes contain some specific provisions for mining safety, yet more generally the matter is left to the inspector's discretion, in concurrence with the opinion of the courts applying common law principles. How far the inspector's recommendations are binding, and how far subject to review by the courts, need not here be discussed; but were a thorough inquiry to be made as to the legal practice of the State on mining safety it would be necessary to ask what are the actual rules and precedents of the inspector and what has been established by the reported cases of litigation.

SAFETY CAGES

"It shall be unlawful for any person to sink or work through any vertical or inclined shaft, where mining cages are used, at a greater depth than 200 ft., unless the shaft is provided with an iron-bound safety cage to be used in lowering

or hoisting employees or any other persons into or from such shaft. The safety apparatus, whether consisting of eccentrics, springs or other devices, must be securely fastened to the cage and be of sufficient strength to hold the cage loaded at any depth to which the shaft may be sunk. The iron bonnet must be made of boiler-sheet iron of good quality, at least 3/16 in. in thickness, and must cover the top of the cage in such manner as to afford the greatest protection to life and limb from any debris or anything falling down the shaft" (Sec. 2581).

A fine not exceeding \$1000 is provided for violation of the foregoing section. (Sec. 2582.)

EXHAUST SYSTEMS

Smelters or dry crushing reduction works are required to put in exhaust fans and dust chambers, or the like, under penalty of \$500 to \$1000 fine and failure to provide them shall be *prima facie* evidence of negligence. The mine inspector must visit such works at least once a month to see that this provision is complied with (Secs. 2583-2586.)

INSPECTOR OF MINES

An inspector of mines, shall be appointed by the governor with the advice and consent of the senate. He shall be not under 30 years of age, practically acquainted with mining in all its branches and not an officer, director or employee of any mining company. He shall have access to all mines provided he does not impede their working during the examination, and the owners, etc., are to render him any necessary assistance but not to bear the expense of the examination.

Upon formal specific complaint of three or more persons setting forth that the mine in which they are employed is dangerous in any respect, he shall examine the mine. He shall serve a certified copy of the complaint, without the names of the complainants, upon the superintendent or manager, before he visits the mine, and if on examination he finds it to be dangerous he shall notify the owner, lessor, lessee or agent and "shall require all necessary changes to be made without delay for the purpose of making such mine safe for the laborers employed therein; and in case of any criminal or civil procedure at law against the party or parties so notified, on account of loss of life or bodily injury sustained by any employee subsequent to such notice, and in consequence of a neglect to obey the

inspector's requirement, a certified copy of the notice served by the inspector shall be *prima facie* evidence of the culpable negligence of the party or parties so complained of. Nothing herein shall be construed to give the control of any mine to the mine inspector or allow him to interfere with the working of any mine."

It shall be the mine inspector's duty, at least once a year, to visit every mining county in the State and examine as many of the mines therein as practicable. He shall make such recommendations as in his judgment are necessary to insure the safety of the workmen, and upon finding a mine to be unsafe shall notify the owner, etc.

In case of a serious or fatal accident in any mine the inspector shall at once be notified and shall proceed to conduct an examination in a manner more particularly set forth. The owner, etc., who shall fail to give due notice shall be fined \$200 to \$1000.

Children under 14 must not be employed in mines.

The inspector shall annually report to the governor all serious or fatal personal accidents, with statistical and other information tending to promote development of the mineral resources of the State.

The inspector shall receive an annual salary of \$1200 with an amount limited to \$1000 for expenses, besides mileage. (Secs. 136-152.)

BELL SIGNALS

At all mines where hoisting apparatus is operated in the State of South Dakota the following code of bell signals shall hereafter be adopted and used:

"One bell, hoist; one bell, stop, (if in motion); two bells, lower men; three bells, hoist men; four bells, blasting signal. Engineer must answer by raising bucket or cage a few feet and letting it back slowly; then one bell, hoist men away from blast. Five bells, steam on; six bells, steam off. Seven bells, air on; eight bells, air off. Three-two-two bells, send down tools. Nine bells, danger signal (fire, accident or other danger). Then ring number of station where danger exists. No person shall ring any signal bell except the station tender, except in case of danger or when the main shaft is being sunk. Engineers must slow up when passing stations when men are on the cage or bucket.

STATION BELLS.

Bells.	Pause.	Bells.	No. Station.
1.	"	1	1
2	"	2	2
3	"	3	3
Etc.	"	Etc.	Etc.
5	"	5	20

"If cage is wanted ring station signal. Station tender will respond in person. If station is full of ore and station tender is wanted ring station signal.

"One copy of this code shall be posted on the gallows frame and one before the engineer." (Laws of 1903, Chap. 181.)

LADDER WAYS

"In all mining shafts 50 ft. or more in depth containing two or more compartments, ladderways shall be constructed in a compartment separate from the compartment in which the cage or bucket runs, and platforms shall be built for landings at every 12 ft., with inclined ladders between said platforms." (Laws of 1903, Chap. 179.)

CALIFORNIA

In every quartz-mining claim where 12 men are employed daily, no shaft on incline shall be sunk deeper than 300 ft. without providing a second mode of egress, by shaft, or tunnel, to connect with the main shaft at a depth of not less than 100 ft. from the surface. (Act of 1872, in General Laws of 1906, Act. 2222, Secs. 1-4.)

Act 2223 (from Laws of 1874) relates to the protection of coal miners and covers such matters as maps, outlets, ventilation, inside overseer and boilers.

Act 2224 (from Laws of 1881) provides for a State hospital and asylum for miners.

Act 2225 (from Laws of 1893) establishes a uniform system of mine bell signals. A miner disobeying this rule cannot recover.

WASHINGTON

The "General Laws," compiled 1897, contain a chapter on "Mines and Mining." (Secs. 3145-3211). Article 3, "Protection of Coal Miners" (Secs. 3158-3185—see also amendments in Session Laws of 1907, Chap. 105) contains numerous provisions for safety. It treats of inspection, maps, number of openings, escape, ventilation, bore holes, signals, hoisting, child labor, boiler examination, explosions, timber, stretchers, tamping tools, etc.

SAFETY CAGES

Article 4 (Secs. 3186-3193) is entitled "Protection Against Accidents from Open Shafts." It contains, however, a section requiring the use of safety cages. Every vertical shaft sunk to a greater depth than 150 ft. must be provided with a safety cage suitably bonneted with boiler sheet iron of good quality, at least 3/16 in. thick, and provided with safety apparatus of sufficient strength to hold the cage loaded at any depth to which the shaft may be sunk.

KANSAS

A fairly copious mining code is provided by the statutes of the State (Gen. Stat., 1905, Chap. 66a, Secs. 4304-4373—see also session laws of 1905 and 1907). While these relate largely to coal mining, for which there are many safety provisions, it will be noticed that Secs. 4333 *et seq.*, which are concerned with that matter, apply to underground workings in general. The regulations here digested

are, therefore, applicable to metalliferous mines.

Rules are laid down for the regulation of break-throughs in coal or other mines operated by the room-and-pillar system. They shall be 40 ft. apart, at least 6 ft. wide and the full height of the vein, when that is 6 ft. or less. They shall be filled with slate rock or closed by brattice to make them air-tight as soon as the succeeding break-throughs are made. Rules are also laid down as to the manner of ventilation and of daily inspection for detection of gas.

STAIRWAYS

"It shall be the duty of the owner, lessee or operator of any mine where the natural strata are not safe in or around all workings, pumping and escaping shafts, to securely case-line or otherwise make said places secure, and all escape-ment shafts shall be provided with stairways securely fastened so as to bear the combined weight of not less than 15 men ascending or descending the same. Said stairways shall be so constructed as not to exceed 45 deg. of elevation by each section of said stair, and each section shall have substantial guard rails securely fastened, and the stairways shall be separately partitioned from the parts of such shafts used as upcasts or downcasts, and the traveling ways between the bottom of the main shaft and the escaping shaft or stairways shall be at least 5 ft. in height. Said traveling ways shall be kept clear of all obstructions, and standing or stagnant water shall not be allowed to accumulate in any traveling way between the upcast and downcast shafts. And in case of mine shafts which are over 150 ft. in depth, where stairways cannot be conveniently constructed, other safe means of hoisting the persons employed in such mine must be kept ready at all times, so as to be available in case of accident to the regular hoisting shaft or machinery in use at the same time." (Sec. 4337.)

MANNER OF ASCENDING

"It shall be the duty of the foreman, cager or whosoever may have charge of the bottom of any shaft, to give the proper signal to the topman and engineer whenever any six employees who work therein are ready to ascend, by day or night, and for the making of such ascent it shall be the duty of the bottom cager to give them an empty cage by which they can ascend. And every road on which persons travel underground, when the coal is drawn by mules, or other power, shall be provided at intervals of not more than 30 ft. with sufficient manholes for places of refuge." (Sec. 4338.)

AIRWAYS

"Airways of sufficient dimensions shall be provided. In no case shall the area of the air course be less than 21 ft. in mines operated on room-and-pillar system. Stag-

nant water shall not be allowed to remain in air courses, entries, traveling ways or rooms. Airways must be kept clear of obstructions. They must be examined twice a week and reported on once a month to the State mine inspector. Air gates shall be kept open no longer than necessary." (Secs. 4339-4343.)

To enforce the foregoing regulations the powers of the inspector, method of procedure and penalties are defined. The law is to be kept posted at or near the top of the mines. (Secs. 4346-4349.)

EDWARD P. BUFFET.

New York, Dec. 16, 1908.

The Elmore Process at Cobar

In G. W. Williams' article entitled "Cobar Gold and Copper Field, New South Wales," in the *JOURNAL* of Nov. 14, 1908, he says: "The Cobar gold mines erected three Elmore units but they have thus far not proved a success." This statement conveys a wrong impression, as the three units erected by the Cobar Gold Company have accomplished all that was expected of them, and indeed more.

The facts in the matter are very simple. The Cobar Gold Company has an ore which is exceedingly difficult to treat. A number of different processes were tried, and, among others, our own. The company appointed Johnson & Sons, of London to investigate the method. A bulk parcel of average ore was obtained and put through our testing plant under Johnson & Sons' immediate supervision. The result of these trials was that the Elmore plant was recommended.

The results obtained in the trials showed the crude ore to contain about 1.25 per cent. copper and about 0.55 oz. gold per ton. From this material an extraction was secured of about 90 per cent. of the copper and about 52 per cent. of the gold, leaving in the tailings from the Elmore plant about 0.15 per cent. copper and about 0.30 oz. gold. Johnson & Sons recommended the cyaniding of these tailings for the recovery of the remaining gold, so that really the Elmore process was intended to be applied in this case for the removal of the copper, the presence of which excluded the possibility of satisfactory direct cyanide work.

The plant in due course was erected, but the old battery which existed on the mine was in a state of great dilapidation, and this expression also fairly describes the power plant. Under such conditions of power and crushing plant, it was naturally impossible to secure continuous running, and as it turned out the battery produced an enormous proportion of slime material. Notwithstanding these obvious drawbacks the Elmore plant actually accomplished the same results on the mine as were secured in our testing plant in London.

We have, therefore, nothing to apologize

for in connection with this installation, but the fact is that, owing to the presence of the very large amount of extraordinarily fine slimes produced from this particular ore by the battery, the Cobar company found it practically impossible to cyanide the tailings from the Elmore plant; and here the whole crux of the question lies at the present moment.

The consulting engineer of the Cobar Gold Company is about to leave for the mine to investigate this matter of the crushing and power plant, and it is hoped that the plant will soon start again with modern power plant and crushing appliances.

J. STOCKER.

London, England, Dec. 9, 1908.

Alunitization

I have read with much interest the two recent articles in the *JOURNAL* of Dec. 5 and 12, 1908, by Robert T. Hill, relating to gold deposits of the alunitic type, and your editorial comment on the significance of the association of alunite and gold. While I am gratified, of course, at the importance attached to the investigations at Goldfield, I feel that a word of caution is necessary. My remarks are not in criticism of Mr. Hill's interesting contributions, but are intended for readers who, it may be supposed, are less trained than he in careful discrimination and deduction.

It is entirely true that the Goldfield type of deposit is new and of unusual interest. It is further true that the presence of alunite is suggestive of chemical activity of a kind that may produce valuable deposits, and that it thus invites attention from prospectors. It should be borne in mind, however, that many of the occurrences of the mineral listed in my original paper* have no connection whatever with gold. Alunite, in short, may form wherever natural solutions of sulphuric acid, especially thermal or strong solutions, react on rocks containing potassium feldspars or sericite. The sulphuric acid may conceivably be derived from various sources. It may be directly volcanic; it may be produced by the oxidation of solfataric hydrogen sulphide; or it may come from the oxidation of pyrite.

The alunite at Cripple Creek, referred to in your editorial, occurs in small quantity and has unquestionably been formed in the oxidized zone by sulphuric acid derived from pyrite and acting probably on sericite. It is accordingly secondary and has no genetic significance as regards the unoxidized ores. The alunite at Goldfield, on the other hand, is very abundant, and its formation is certainly connected with the genesis of the rich ores. The precise nature of that connection is still under investigation and will, I hope, be

*"The Association of Alunite with Gold in the Goldfield District, Nevada." *Economic Geology*, Vol. 2, 1907, p. 687.

explained in a full report on the Goldfield district now nearing completion.

The scientific worker is occasionally surprised by the readiness with which others attach practical importance to and draw sweeping conclusions from what to him is an interesting and suggestive, but not necessarily a revolutionary, discovery. This rapid application of new light to practical ends is, of course, most likely to outrun discretion where the illumination can supposedly be at once directed to so attractive an object as a rich gold deposit.

F. L. RANSOME.

Washington, D. C., Dec. 20, 1908.

The Origin of Coal

To the reasons urged by Hiram W. Hixon, in the *JOURNAL* of Aug. 1, 1908, in favor of a deep sea origin for coal, may not the usual presence of a bed of fire clay, immediately under the coal, be added?

It is difficult to imagine an abundant vegetation having its roots in such a clay and deriving any sustenance from it, while the origin of the fire clay, as a deep sea deposit is much more probable.

EDGAR HALL.

Silverspur, Queensland, Oct. 23, 1908.

Acetylene Lamps Underground

Acetylene lamps, according to W. F. Slaughter (*Proc.*, Lake Superior Min. Inst., Vol. XIII, p. 206), consume about one-fifth as much oxygen as candles do when giving the same amount of light. On that account, when it is necessary to work in badly ventilated stopes or headings, acetylene lamps should be used, not only because they consume less oxygen, but also because they give a bright light in air in which it is difficult to make a candle burn. Acetylene lamps are now made small enough to be worn on a miner's hat; they are used at the Saginaw mine on the Menominee range, Michigan. While the lamps require some attention in order to keep the water feeding properly to the carbide, the miners soon learn how to care for them. The lamps then give little trouble. It is said that it costs about two-thirds as much for light when acetylene lamps are used as against candles. At the Michigan mine the cost of the carbide required to last a 10-hour shift is about 2 cents.

The frequent use of water for spraying in the carbonate workings and the compulsory use of water jets for machine drilling, according to the report for 1907 of the Department of Mines, New South Wales, page 89, has had a very beneficial effect in diminishing lead poisoning at the Broken Hill mines.

Personals

Mining and metallurgical engineers are invited to keep *THE ENGINEERING AND MINING JOURNAL* informed of their movements and appointments.

C. W. Purington, who has been visiting New York and Boston, sailed Jan. 9 for London.

Edward K. Judd, of New York, mining engineer, is in Sonora, Mexico, on professional business.

Edward H. Cook, mining engineer, has removed his office from Tucson, Arizona, to El Paso, Texas.

Charles Sweeney has resigned his position as president of the Federal Mining and Smelting Company.

G. W. Wertz, recently in the Ceur d'Alene district, Idaho, has taken charge of the Southern Gold mine at Gold Hill, North Carolina.

Harry D. Quinby, of Denver, Colo., has arrived at Gold Hill, N. C., to install the Elmore oil vacuum concentrating process at the Union Copper mines.

Dr. William B. Phillips, of Birmingham, Ala., has just spent a month examining the brown-ore lands in western Kentucky owned by the Hillman Land and Iron Company, of St. Louis.

Herbert C. Hoover, of London, was in New York last week. He went to San Francisco Jan. 8, and expects to return about Feb. 1. He is to give some lectures on mine finance to the students of Columbia University.

S. S. Rosentamm, representative of Adolph Lewisohn, of New York, who recently acquired control of the Kerr Lake mine, Cobalt, visited the property recently, accompanied by Benjamin B. Lawrence, consulting engineer.

Henry P. Louttit has resigned his position as mine inspector of the First Bituminous district of Pennsylvania. It was in this district that the Marianna mine explosion occurred recently. His successor is William H. Howarth, of Mount Pleasant.

Reginald Meeks, metallurgical engineer, who has been connected with the staff of the *ENGINEERING AND MINING JOURNAL*, has resigned and will be associated with Dr. Charles T. Hennig, managing the latter's testing and research plant in East 35th street, Brooklyn.

William B. Dickson, heretofore second vice-president, has been chosen first vice-president of the United States Steel Corporation, in place of James Gayley, resigned. His successor as second vice-president is David G. Kerr, heretofore manager of the iron-ore interests of the Carnegie Steel Company.

W. A. Carlyle has been appointed professor of metallurgy at the Imperial College of Science and Technology, London, to succeed Professor Gowland. He is a

graduate of McGill University, Montreal, 1887, and was a professor there 1891 to 1895. He has had practical experience in Colorado, in British Columbia and as manager of the Rio Tinto mines in Spain, and was Provincial mineralogist of British Columbia for three years.

James M. Swank has tendered his resignation as secretary and general manager of the American Iron and Steel Association, to take effect on the election of his successor. Mr. Swank was largely instrumental in the organization of the association; has been its secretary for 36 years and general manager also for 22 years. His retirement will be regretted by the many who appreciate the value of his hard and constant labors for the association and the care and fidelity with which he has collected and arranged the statistics of the trade.

Obituary

Frank Taylor died at Watford, England, Dec. 25, aged 59 years. He was connected all his active life with the well known firm of John Taylor & Sons, of London. For 18 years he had special supervision of the Australian interests of the firm.

Walter Richardson Crosby died in Berkeley, Cal., Jan. 2, aged 49 years. He was for a number of years connected with the Venable Construction Company, Atlanta, Ga., in the execution of important engineering works. Five years ago he went West, taking charge of the Butters Reduction Works at Virginia City, Nev. Two years ago he was made general manager of the Butters mining and metallurgical interests, with office at San Francisco.

Herman Justi, one of the best known men in the Western coal trade, died at Chicago Jan. 1, aged 56 years. He was born in Kentucky and lived in that State and Tennessee for 46 years, having been engaged in business on a considerable scale. As a chief of publicity of the Tennessee Centennial Exposition in 1897 he found temporary field for the exercise of his undoubted talents. Coming to Illinois the year following at the instance of his friend, the late W. P. Halliday, of Cairo, then a leading coal producer of southern Illinois, Mr. Justi helped found and for 10 years successfully and ably administered the affairs of the Coal Operators' Association. The problem of labor and capital deeply interested his mind and he wrote several valuable monographs on labor questions. As commissioner of the Illinois association he helped to settle many disputes, and secured many concessions from the miners, who had much confidence in his fairness and honesty.

James Corrigan, head of the firm of Corrigan, McKinney & Co., died at Cleveland, Ohio, Dec. 24, aged 60 years. He was born in Morrisburg, Ont., and as

a boy went to Cleveland and found employment on a lake schooner. Later he engaged in the oil business, but afterward sold out to the Standard and entered the shipping trade, acquiring a considerable fleet of vessels. James Corrigan was one of the earliest to recognize the possibilities of the Lake Superior iron country, and it was a natural step from the carrying of ore to the mining and smelting of it. He became a consistent buyer of Lake Superior ore properties, and at the time of his death was the most extensive independent operator on the ranges. On the Mesabi range the firm owned the Admiral, Commodore, Jordan, St. James, St. Paul, Stevenson and Wallace mines; on the Gogebie, the Colby, Colby No. 2, Ironton, and Ironton No. 2; on the Menominee the Armenia, Baker, Basic, Crystal Falls, Dunn, Fairbanks, Genesee, Great Western, Groveland, Kimball, Lamont, Lincoln, Paint River, Quinnessee and Tobin; on the Marquette the Star West mine. The firm also from time to time acquired interests in blast furnaces. Their holdings included the Genesee Furnace Company, at Charlotte, N. Y., the Scottdale Furnace Company, at Scottsdale, Penn., and the Josephine Furnace and Coke Company, at Josephine, Penn. At Josephine, the firm founded a town as well as a furnace. He had also planned to build a new furnace on the Cuyahoga river at Cleveland, under the name of the River Furnace and Dock Company. This is expected to be in operation in 1910. In recent years the firm gradually withdrew from the ownership of vessels, devoting attention more especially to the operation of mines. Mr. Corrigan also in recent years acquired large interests in copper mines in Mexico.

Societies and Technical Schools

Mining and Metallurgical Society—The annual meeting was held Jan. 12, at Columbia University, New York.

American Institute of Mining Engineers—The 96th meeting of the Institute for the reading and discussion of papers will be held at New Haven, Conn., beginning Feb. 23. Professor J. D. Irving, Yale station, New Haven, Conn., is secretary of the local committee of arrangements. A complete list of the papers to be presented at this meeting cannot be given; but it may be said that, among the leading topics of discussion, according to present expectation, will be: Professional Education (in connection with the inspection of the new Hammond laboratories, etc., of the Sheffield Scientific School); the Conservation of National Resources; and the Construction of a Sea-Level Panama Canal (in connection with a paper by Henry G. Granger, to be published in the January *Bulletin*). Various entertainments and visits to works in and near New Haven have been planned.

News of the Industry Reported by Special Representatives at
San Francisco, Butte, Goldfield, Nev., Denver and Toronto

REVIEWS OF IMPORTANT EVENTS

San Francisco

Jan. 8—A short time since mention was made in one of these letters of a merger of gold-dredging companies under the name of the Natomas Consolidated, taking in all the dredging interests near Folsom and some at Oroville. The capital stock of the corporation is \$25,000,000 and bonds to a large amount are issued, the cost of purchasing the dredge interests in question being some \$7,000,000. It was thought at the time that more or less of the capital required would have to come from Eastern sources, but at a meeting held in this city last week it was found that enough had been subscribed here. Eastern men who wished to become interested were unable to come in, as the California subscriptions were sufficient.

Action has been commenced in the United States Circuit Court in this city against the Trinity Bonanza King Mining Company for \$2174, the value of certain Government timber alleged to have been cut for use in the mine for lagging and timbers. The timber was sugar pine and red fir. The miners have to be careful in these days where the timber supply comes from, even when they buy it from people supposed to own the land where it grew.

The Northern Electric Railway Company is endeavoring to have the city officials of Oroville modify in some manner the injunction against the Indiana Gold Dredging Company, to avoid prospective trouble with that company. The right of way of the Northern Electric Company runs over the dredging company's land and when the right was secured the railway people agreed to let the dredge cut through their track line; but this was to be cut only once. Since the city's injunction against the dredging company that company has changed its plan of dredging, and this involves three cuts instead of one, thus involving great expense on the part of the railway company.

Work is about being started by the Metropolis Construction Company on the contract to build the impounding reservoirs or settling basins planned by the Government engineers as part of the scheme to relieve the waters of the Yuba river of debris near the town of Hammond, where the gold dredgers are operating. Each settling basin will have an area of 1000 acres. In addition to the exact uses to which the basins are to be put, some advantage will be derived by the dredge operators at that point, above Marysville.

Quite heavy rains this week have suc-

ceeded the freezing days of last week in the mining regions of the State. There is still, however, some trouble with snow in the ditches and in the higher ranges there is much ice to contend with.

The Seal of Gold Mining Company in Virginia Dale district in the southern part of the State recently leased its group of mines to H. R. Slater. One of the directors subsequently instituted suit in the name of the company to have the lease canceled. The judge of the district court has now settled the matter by deciding that Slater has a right to his lease. W. L. Peters, of Riverside, is president of the company.

Goldfield, Nevada

Jan. 5—The State bullion-tax collector estimates the gold production of Nevada for 1908 at \$14,000,000, this amount being calculated from the actual production of \$10,019,730 for the nine months ending Sept. 30.

Dividends paid by Goldfield properties for the past year amount to \$1,578,500 made up as follows: Florence Goldfield, \$420,000; Engineer's lease, \$570,000; Rogers Syndicate, \$300,000; Mohawk Jumbo, \$78,000; Frances Mohawk \$45,500; Florence Annex, \$50,000; Red Top Consolidated, \$20,000; Little Florence, \$30,000; Mohawk Combination, \$65,000. Considering the inactivity of the two largest properties—the Consolidated and the Florence—pending the construction of their mills, this is a very creditable showing.

The Goldfield Traction Company last week commenced work in Columbia for the trolley system; grading will be carried on from that point into Goldfield where the road will traverse the principal business and residence streets while another loop will cover the mining territory to the east of town. The management expects to have six miles in operation by July 1, 1909.

Charles S. Thomas, ex-Governor of Colorado, and W. H. Malburn are reported to have withdrawn from the firm of Thomas, Bryant and Malburn. This firm has been legal adviser to the Goldfield Consolidated Company since it was formed. H. S. Bryant, together with J. P. O'Brien, former district judge of Nye county, under the firm name of Bryant & O'Brien, will continue as legal advisers to the Consolidated.

The Fish Lake valley oil excitement continues and that vicinity is the scene of considerable thousands of acres have

been located, one syndicate alone holding over 50,000 acres. Oil shows at surface in a number of places; this oil is claimed to have a paraffin base. Fish Lake valley is about 75 miles west of Goldfield near the line between Nevada and California.

Butte

Jan. 7—The report of the State coal mine inspector for 1908 has been made public. The report calls attention to what the inspector calls the criminal disregard for the welfare of the coal miner, and advocates a more thorough regulation by law of the safeguards necessary for the miner's protection. The production of coal for the year ending Nov. 1, 1908, was 1,979,217 short tons, a decrease of 2.5 per cent. The fatalities for the year were 12 and the number of injured was 51.

The annual report of the Butte Mining Stock Exchange for 1908 shows an increase in the number of shares traded in during that period as compared with the previous year, although the values represented were less. There were sold on the exchange 1,593,345 shares of stock, valued at \$455,740, during 1908, as compared to 1,530,183 shares, valued at \$560,007, in 1907.

A reorganization has taken place in the lines controlled by the Chicago, Milwaukee & St. Paul Railway. The original corporation, which is organized under the laws of the State of Wisconsin, retains the same name, but the subsidiary companies, formerly known as the Chicago, Milwaukee & St. Paul railways of Washington, Idaho, Montana and South Dakota respectively will cease to have independent organizations and the entire line from Mobridge, on the Missouri river to Seattle will be controlled by the newly organized Chicago, Milwaukee & Puget Sound Railway, a Washington corporation. The entire stock of this company, capitalized at \$100,000,000, will be held by the Wisconsin corporation.

Denver

Jan. 9—In the Cripple Creek district, the Portland Gold Mining Company advertises that it will now buy all grades of Cripple Creek ores, paying cash, and giving lowest treatment rates, though the rates are not quoted.

At Stratton's Independence, an initial run is to be made of 50 tons daily of low-grade ore in the dry mill. The concentration plant is to be run 30 days later.

A suit has been filed again Stratton's

Independence, Ltd., in the United States Circuit Court in Denver, by the Portland Gold Mining Company to recover \$366,000, alleged to be the value of ore illegally extracted from the latter's territory. This is an old suit revived.

The suit against the county commissioners of Teller county for a readjustment of assessment on their properties by 40 mining companies as plaintiffs, has been commenced.

A report on the estate of the late W. S. Stratton, discoverer of the Independence mine, shows a value of \$6,418,190, as against \$6,307,166 at the time of his death. It is stated that the estate will be wound up at once, and the building of the Myron Stratton Home commenced.

One of the toughest mining fights ever waged has just been won by Allen L. Burris, a young man under 30 years of age, who, after a 12 years' struggle, has wrested the control of the El Paso Consolidated company from the Bernard faction. The property consists of about 65 acres on Beacon hill, in the Cripple Creek district, and has paid upward of a million and a quarter of dollars in dividends. The victor was backed by Eastern capital, and from being trammer underground, has risen to be president and general manager of the company.

The Moose Gold Mining Company is reported to have sold the Trilby and Ben Harrison claims to the Trilby Gold Mining Company, and to have thereupon declared a dividend of \$85,000. The Moose was one of the early bonanzas of the Cripple Creek district, but has been idle for many years on account of the deadly gases encountered in the lower workings.

Toronto

Jan. 8.—The wagon road to Gowganda is being rapidly pushed forward by the Canadian Northern Railway from Sellwood, the end of the railroad being built north from Sudbury, to the new camp—about 42 miles. The railway announces that its traffic department will receive freight for Gowganda from any Canadian point. This will be forwarded by rail *via* Sudbury to Sellwood, and there sent on by the company's teams to Gowganda.

The total output of ore forwarded to the smelters from Cobalt during 1908 is given as 25,463 tons, as compared with 14,851 tons for 1907. The increased value, however, is considerably greater than these figures would indicate, and a considerable proportion of the shipments last year were concentrates, and less lower-grade ore was sent. The total number of shipping mines was 32, the principal shippers being La Rose 4715 tons, Nipissing 3557; O'Brien, 3428, and McKinley-Darragh 1871 tons.

An expedition is being fitted out at Elk City under direction of Thomas Saville, a well-known guide and prospec-

tor, to look for a new silver field west of Gowganda. Mr. Saville claims to have obtained certain information as to its existence from the Indians of the region with whom he was associated for many years.

The Ontario government has issued an Order-in-Council withdrawing from prospecting a large area in the Gowganda district. This includes all the lands not already staked in the townships of Haultain and Nicol and two other as yet unnamed townships 50 miles north-west of Cobalt and 20 miles from James township; the area affected contains about 140 square miles. The bottoms of all lakes in the district and a strip of land 66 ft. wide around all lakes are also withdrawn. Among some of the lakes affected are Gowganda, Abusking, Wigwam, Everett, Bloom, Miller and Leroy. The order exempts all claims staked out before December 18. About two-thirds of the townships specified have already been taken up and Miller and Leroy lakes have also been largely staked. It is probable that the areas withdrawn will be offered for sale subject to royalties.

In several of the cases against mining companies for violation of the law regarding prospectuses an arrangement has been arrived at, under which a statement of facts will be submitted to the magistrate, and should he decide to convict, a stated case will be submitted for the decision of a higher court.

Johannesburg

Dec. 20.—When the introduction of very heavy stamps was first attempted by the Consolidated Gold Fields, considerable opposition was raised to the principle, both by practical mill men and consulting engineers. Gradually, however, their special applicability has been clearly revealed and different interests appear to be rivaling each other in their efforts to install the weightiest stamps on the field. A mine in the Krugersdorp district—the West Rand Consolidated—is now about to install an additional 20 stamps weighing 1850 lb. each, for an estimated duty of 12 tons per stamp per day. This will constitute a record for gravity stamp work. It may be pointed out that the duty factor is dependent upon size of screening, and that comparisons of duty provide no test of efficiency, for regrinding has to be undertaken in tube mills as auxiliaries. In all cases, however, a limitation to very coarse crushing in the stamp battery is apparent, owing to the invariable use of amalgamating tables between the stamps and the tube mills. The heaviest stamps now actually in operation on the Rand are those of the Simmer Deep—1670 lb.—which have been working satisfactorily for two or three months. The East Rand Proprietary mines are now also adopting this standard of stamp weight.

Three or four years ago there raged a fierce controversy among certain medical men and chemists as to the cause of the sicknesses associated with underground life on the Rand, and those who maintained that gases and bad ventilation were inadequately appreciated factors and that dust was too constantly defined as the basis of all ills, are apparently ahead. Additional support has been provided by Mr. Cullen, who—as manager of the Modderfontein dynamite factory—spoke with familiar authority on "The Gases Resulting from the Use of High Explosives," and did not hesitate to emphasize the points of blemish in connection with blasting practice on the Rand. A result of Mr. Cullen's investigations on the field has been to indicate that there is a greater evolution of carbon monoxide by the detonation of blasting gelatin—the staple "powder" of the Rand—than is generally supposed. The points of importance are that the anti-fume mixtures or neutralizers are valueless; that clay tamping gives better results than sand cartridges; that fresh gelatin gives no better results than that three months old; that within this age limit, No. 6 detonators are as serviceable as No. 8; that blasting gelatin is improved by extra oxygen in its composition; that ordinary time fuse vitiates the mine atmosphere to a great extent; and that electrical firing not adopted in Rand working practice, gives better results than time fuse.

A promising addition to the constitution and rules of the Chemical, Metallurgical and Mining Society has been proposed which carries still further the idea of expansion. The scheme is for the formation of local sections in any district, in South Africa or not, where at least 20 members or associates reside and are anxious to hold meetings for the discussion of questions. The special advantages to outside members will be the use of the Society's *Journal* for the publication of proceedings, while they will also, of course, benefit by the influence and reputation of the parent body. The chairman of the local committee shall be vice-president of the general society and the local secretary a corresponding member of council. Reports of proceedings and papers contributed at section meetings will be edited and the expense of publication borne by the general funds, from which a grant may even be made, if the work undertaken is of interest, toward the expenses of maintaining the local sections. The society has already corresponding members of council in England, Colorado, Mexico, Sumatra and Queensland.

The Transvaal University College decided to establish a travelling scholarship for the student who comes first in the four-years' mining course. A sum will be provided to enable the successful graduate to visit any other mining field in Europe or America, to gain special influence in any approved line of study.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Arizona

GILA COUNTY

Miami—Plans are being made for a 2000-ton concentrator and a short line of railroad will probably be built this winter. A 120-ft. crosscut on the 570-ft. level is reported to be in 3 per cent. ore. A crosscut on the 800-ft. level is also in ore.

GRAHAM COUNTY

Detroit Copper—This company has installed new boilers and crude-oil burners in the heating plant at the concentrator. The old tunnel which connects the mines and concentrator with the smelter has been widened to accommodate 36-in. gage cars. This saves much transferring of coal and heavy machinery to the small cars formerly in use.

Arizona Copper—Concentrator No. 6 at Morenci has been enlarged. A large amount of money is being expended for the improvement of the trails for the benefit of the workmen.

Chase Creek—This company plans to extend the 2000-ft. tunnel another 1000 feet.

PIMA COUNTY

Imperial Copper Company—The report for the six months ending Sept. 30, 1908, shows that the company produced 4,109,078 lb. of copper and 62,728 oz. of silver. The company has blown in the second unit of its smelter and in December, 1908, turned out 800,000 lb.; January's output should be 1,000,000 lb. Conditions at the mine and smelter have been bettered during the past year, more ground has been opened, a large tonnage mined, capacity of the smelter doubled, and everything put in readiness for increased operations. An additional unit has been installed at the smelter, bringing the capacity of the plant to about 700 tons. In payment for the additional unit the company has received \$100,000 additional capital stock of the smelting company, making a total of \$900,000 held by the Imperial. The balance sheet as of Sept. 30 shows an item of \$2,000,000 bonds and bills payable of \$602,305, held entirely by the majority stockholder, the Development Company of America. Accounts payable amount to \$148,960.

SANTA CRUZ COUNTY

Red Hill—At a point 285 ft. in the tunnel on the opposite side of the hill a body of chalcopyrite has been opened. The

main tunnel cut into an ore body 420 ft. from the portal, thus indicating an ore zone 600 ft. wide. Drifts are being run east and west from this main tunnel.

Pittsburg Mine—The shaft is down about 200 ft. At 160 ft. a crosscut went through 8 ft. of low-grade ore. Ore is reported in the bottom of the shaft.

YUMA COUNTY

Clara Consolidated—Two new strikes are reported on the Morro group, carrying about 7 per cent. copper and considerable gold. Work is progressing on two inclined shafts.

California

ALAMEDA COUNTY

Phoenix Quicksilver Mine—This mine, not far from Livermore, after three years idleness is to be started up again by a new company composed of M. J. Laymance, S. A. Knapp and other Oakland men. The works are being cleaned up and the retorts repaired. The mine has never made any product, but at the time of the death of Alvinza Hayward, its principal owner, was about to become productive.

AMADOR COUNTY

Argonaut Mining Company—A new station is being cut on the 3000 level of this mine at Jackson. The Hoffman field ground is expected to yield largely in the future.

CALAVERAS COUNTY

Four Hundred—This mine near Mountain Ranch is being opened by Oakland men under superintendence of A. Mauna. The rock is expected to mill from \$6 to \$10 per ton. A steam hoist will shortly be installed.

EL DORADO COUNTY

Snow—This property near Newtown, which has been tied up in an estate for some years has been bonded by B. G. Haskell, C. A. Pugh and others of San Jose. There is a large gravel channel underlying this ground and it is now to be worked.

HUMBOLDT COUNTY

Gem—At this placer mine, 10 miles from China Flat, B. G. Steele and others are preparing to operate a No. 3 giant. A new device of Mr. Steele's to save the gold and platinum is being installed.

INYO COUNTY

Four Metals Company—The smelter of this company at Keeler is handling something over 150 tons daily of slag from the old furnaces. When the aerial tramway is finished, Cerro Gordo ore will be smelted.

MARIPOSA COUNTY

Mariposa Commercial and Mining Company—This company now has three mills crushing rock, most of the ore coming from leases on the company's mines.

MONO COUNTY

Wild Rose—H. G. Lowers and others are starting up this old mine eight miles west of Benton.

NEVADA COUNTY

Golden Gate—At this mine, Grass Valley, a new 10-stamp mill, centrifugal pump, and other improvements have been added to the equipment. The mine is an old one and was reopened a year ago by C. C. Haub, but has been taken off the lessees hands by the present company. Electric power is to be used. W. H. Martin is the superintendent.

PLACER COUNTY

Harlow—Laird and the Quinn Brothers have nearly completed the mill at this mine and will shortly commence crushing cement gravel. The mine is near Rocklin.

Orpheum—This company in Ophir district is putting the gallows frame over the new two-compartment shaft and will soon install an electric power plant.

PLUMAS COUNTY

Long Valley Mines Company—At this property, purchased this season by Capt. Adams and associates, the ore taken out is about to be milled. It is probable that work will continue all winter.

SAN BERNARDINO COUNTY

Anaconda—In this mine, near Twenty-Nine Palms, owned by the Mohawk Herald Company, high-grade ore has been struck in the shaft. This is in Gold Palms camp, five miles from the quartz mill at Twenty-Nine Palms.

SHASTA COUNTY

El Dorado—At this mine, near the Tower House, owned by E. P. Connor & Son, and under lease to Sherb Brothers, of Redding, a small mill is being erected.

SIERRA COUNTY

Gray Eagle—A new aerial tramway is being built from this mine to the mill.

Brush Creek and Auto-Up—These two claims near the Mountain House have been bonded to L. L. Battery, of St. Louis, and L. A. Armstrong has been appointed superintendent. These are old mines once profitable, but long idle.

SISKIYOU COUNTY

Grouse Creek—This company is putting in a large flume and will start up as soon as there is sufficient water.

Gardner & Weed—This big hydraulic claim in Quartz Valley has been completely fitted up and a large amount of gravel can now be handled.

TEHAMA COUNTY

Tom Head Copper—A large ledge has been found in the lower or 300-ft. tunnel. Considerable underground work is being done this winter, but no machinery is running.

TRINITY COUNTY

Gem—At this gravel mine, 10 miles above Willow creek, in the old channel of the main Trinity river, the operators have installed a new plan of handling the rock and other debris by means of machinery driven by a Pelton wheel.

TUOLUMNE COUNTY

Central Mother Lode Mining Company—This company has been incorporated with E. C. Kavanaugh as general manager. A force of men has been set at work on the Mangante claim.

Kanaka—This quartz mine, with its mill, has been sold by C. M. Lindsay to Agnes D. Parr, of London, England. A water right is also included in the sale.

Kinkard—Cadamaroti, Lambert & Ryland have leased this mine on the Ryland ranch three miles from Sonora.

Santa Ysabel—Good ore has been encountered in this mine, near Stent, and the 10-stamp mill is again running. Ten more stamps are to be added.

Tarantula—C. F. Crawford and associates, owning this mine near Chinese, have ordered a compressor and machine drills and will continue the main tunnel. Rich rock has recently been struck.

Colorado

CLEAR CREEK COUNTY

Banner Consolidated—This company, operating near Idaho Springs, is planning the erection of a 500-ton concentrating mill; also development along heavier lines.

GILPIN COUNTY

A. K. R. Gold Mining Company—Gold retorts weighing nearly 300 oz. were sold to the Denver mint during December, the gold bringing the unusual price of \$10.80 per oz., believed to be the highest grade

amalgam gold purchased by the Mint from any mine in Colorado. The concentrates also are exceptionally rich, the last carload shipment selling to the Argo smelters for \$90 per ton. New machinery, consisting of air compressor, boiler and engine, is being installed and an additional battery of five rapid-drop stamps is to be added to the mill. George M. Ashmore, Rollinsville, Colo., is manager.

Oh Be Joyful—Denver people have become interested in a lease and bond and are erecting a new shaft building and installing machinery. C. H. Chase, Miners' Exchange building, Denver, Colo., is manager.

LAKE COUNTY—LEADVILLE

Garbutt—From the lower levels this mine, Breccia hill, is shipping 30 tons daily of a good grade of iron sulphides and copper sulphides; the ore carries gold in addition to copper.

Helena—In this mine, Iowa gulch, a station is being cut at the 700-ft. level, where a large pump will be installed. When the station is cut sinking will be resumed; the depth of the shaft is now 720 ft., with 80 ft. still to go. In sinking several streaks of ore have been encountered, which will be developed later. As the shaft gains in depth the formation changes.

Majestic—This shaft, Mosquito range, is now down 100 ft. and a contract has been let to sink another 100 ft. The vein has been caught, and when the shaft reaches a depth of 200 ft., the owners expect to have shipping ore. The property adjoins the London, and the shaft is being sunk on that fault.

Progressive—In this mine, on North Fryer hill, the work which has been carried on in the lower levels for the past two months has developed a body of ore that bids fair to becoming a permanent shoot. In the north drift the ore has been opened and is now over the whole face of the drift, running well in silver and 60 per cent. lead. The orebody is being developed as quickly as possible.

Granite Tunnel—This enterprise is being driven from Granite in the direction of Leadville and is in several hundred feet; several veins have been cut, but none mineral bearing. During the week a vein, several inches wide, was encountered running high in gold. The enterprise is financed principally by local men.

Progressive—In this mine, North Fryer hill, with the new plant of machinery recently installed the lessees have been enabled to unwater the shaft, and are now handling the flow of water with ease. Drifts are being driven into new territory and from present indications the lessees are likely to catch the orebodies that trend through this section of the district.

Gallagher—A good body of ore has been opened in the old workings, Graham park, and as it carries considerable lead it is

welcomed at the local smelter; the silver is also high. From this body 20 tons a day are shipped. Now that the old shaft has been cleaned out and retimbered, it is the intention of the leasing company to sink a new shaft to the north.

Half Moon Group—A company of local men have organized a company to operate this group of claims, Robinson, and work will be started within a few days. The group adjoins the famous Robinson mine.

Progressive Shaft—The body of ore recently opened in this shaft, North Fryer hill, is looking so well that the lessees have decided to sink the shaft deeper and open the orebody at greater depth. Ore shipments are being made to the local smelter.

Yak Tunnel—December was the banner month of the year as far as breaking ground in this adit was concerned; 358 ft. were driven in 30 days. The tunnel is now into Resurrection No. 1 shaft, and in a few days it is expected that several large bodies of water will be tapped. During the run from Ibox No. 4 shaft to its present breast the tunnel has cut four veins in the granite, all carrying gold.

TELLER COUNTY—CRIPPLE CREEK

Gold Sovereign—At the annual meeting last week the present management was successful, voting 926,000 shares, against 528,000 for the opposition, or Rapp party. The directors chosen were J. N. Auer, O. H. Hines, Le Mars, Ia.; M. F. Wendling, Quincy, Ill.; Henry Sachs, Colorado Springs, Colo.; E. J. Boughton, C. G. Jackson, H. L. Shepherd, Cripple Creek, Colo. Resolutions were passed approving the policy of the directors of the last year and deprecating and disapproving the action of the previous board in the granting of a lease on the properties to the Franklin Leasing Company. The board elected O. H. Hines president; M. F. Wendling, vice-president; H. L. Shepherd, treasurer; C. G. Jackson, secretary.

Mary McKinney—The Western Investment Company, leasing this mine on Raven hill, has found a promising vein, said to be of large size, in a crosscut run west from the shaft at the 500-ft. level. The vein is vertical.

Agnes—Work has been begun on this company's Four Brothers claim on Beacon hill. Machinery has been installed in the shaft-house and other preparations made. Eastern parties will operate the claim under lease.

Gold Dollar Consolidated—The Union Leasing Company, operating the Husted shaft of this company on Beacon hill, is shipping steadily ore taken from the large orebody between the 300-ft. and 400-ft. levels.

Londonderry and Manhattan—The claims owned by these companies on Bull, Gold and Ironclad hills have been placed

in charge of J. W. Parfat as resident manager. He will examine and report on these claims, and it is understood that he will have authority to lease blocks of the ground when the examination is completed.

Pike's Peak—In this mine, owned by the Stratton estate, two sets of lessees, Myers & Co. and Schoolcraft & Co., are operating, and are shipping ore.

Idaho

BOISE COUNTY

Gold Hill—The company, E. E. Carter, manager, is arranging for leases on its surface workings, the ore to be treated in the Iowa mill. A power line is to be installed and machinery driven by electric power from the Payette river. Tests have proved that the ores can be cyanided with advantage.

Last Chance—The Columbia Mining Company operating this mine in the Quartzbury district has made a rich strike in the lower adit.

SHOSHONE COUNTY

Amy Group—T. W. Hunt and a number of Eastern associates are negotiating at present for the purchase of this group of claims on the west side of Pine creek. The price is said to be \$25,000. The property has been extensively developed and one foot of clean shipping ore and several feet of concentrating ore opened up.

Atlantic—After an idleness of from four to five years this company has been re-organized and has purchased a group of seven claims in Cedar creek. A force of men is at work.

Evolution—Two feet of solid galena has been encountered on the 290-ft. level of this property. The crosscut from the bottom of the shaft was run about 100 ft. when it intersected the vein which has been crosscut for a distance of about 40 ft. on its dip.

Federal Mining & Smelting Company—A dividend of 1½ per cent. has just been declared on the common stock of this company, and involves a distribution of \$150,000, the capitalization in common stock being \$10,000,000. This is the only dividend that has been paid on common stock since about this time last year. The total now paid on common stock since the incorporation of the company is \$2,643,750. On its \$20,000,000 of preferred stock the company has disbursed this year \$630,000 and a total in all of \$3,934,250.

Flagstaff—At the annual meeting of the stockholders of this company held in Wallace, the following officers and directors were elected: President, J. S. Thomas; vice-president, Joseph Cook; secretary-treasurer, F. T. Millichamp and directors C. G. Matthews and O. B. Wallace. A financial statement showed that the com-

pany has still 130,000 shares of treasury stock on hand. It is believed that a resumption of work will be made in the near future. Development of the company's property ceased about one month ago.

Gold Back—At a depth of about 100 ft. this company has encountered 18 in. of solid, shipping galena together with several feet of good milling ore. The claims of the company adjoin the Pilot mine on the north and the Cornucopia on the south.

Hecla—This company has declared a dividend for the month of December at the rate of 3c. a share. This is the 60th dividend declared by the company and involves the disbursement of \$30,000 making the grand total paid out by the company \$1,710,000 and the total for 1908, \$190,000.

Uctor—Contracts for 350 ft. of work have just been let on the property of this company. These contracts are for a 250-ft. crosscut to the north vein and 100 ft. of drifting on the south vein which has just been encountered. Bonds have been taken by the company on two adjoining claims.

Hugo—An orebody carrying copper and gold has been encountered in the property at a point 75 ft. from the portal of the upper tunnel where a 40-ft. winze had been sunk.

King Solomon—After having been closed for about six months work on this property has been resumed and a contract let for 200 ft. of work. It is believed that in about another 60 ft. the ledge will be encountered when the balance of the work will be taken out in drifting.

Lead Tariff—Frederick Burbidge, representing the mining interests of the Cœur d'Alenes, has placed in the hands of Chairman Payne of the congressional committee dealing with the tariff revision at Washington, D. C., a formal brief containing the protest of the operators of this district against any attempt to reduce the tariff on lead ores.

Montana-Standard—The development of this property has practically ceased for the winter. It is the intention to put a full force of men to work again in the early spring and to erect a concentrator.

Indiana

WARRICK COUNTY

While drilling a test well for oil on the Barkley farm in the northern part of this county, the drill passed through four veins of coal, two of which are 7 ft. thick. The last one is 600 ft. below the surface, and coal brought up is said to resemble camel coal. All the veins have good roofs. The discovery has aroused considerable interest and steps will be taken at once to develop the new field. Jesse Barkley, of Lynnville, owns the land.

Michigan

COPPER

Isle Royal—The new shaft this company is sinking on the Baltic lode is down about 50 ft. in solid ground and sinking has been temporarily suspended while a concrete collar is put in. At shafts Nos. 4 and 6 the hoisting equipment will be ready to go into commission in the course of a few weeks.

Hancock—Drifts on the West Hancock lode which has been opened by means of crosscuts from the 9th, 10th, 11th, and 13th levels of No. 1 shaft are breasted in fine copper-bearing ground. No. 2 shaft will cut this lode at a depth of about 2000 ft. The working crosscut from the 13th level of this shaft will connect with No. 1.

Winona—Operations at No. 3 shaft of this property have been temporarily suspended and the working force transferred to No. 4; No. 3 shaft has been opened to the 15th level and it is now planned to center all activities at No. 4 and open this shaft in like manner, so that when stamping begins, which in all probability will be the coming spring, the company will have ample ground opened to maintain regular shipments. The lode opened at depth shows encouraging mineralization.

Atlantic—Section 16 shaft of this company is nearing the 20th level, and a crosscut from the 19th is entering the lode. Results will be awaited with interest as it is believed the shattered and disrupted condition found in the upper levels will be eliminated with depth.

Franklin—Drifting from the 24th level of this company shaft on the Pewabic lode is under way, and the same richness that was opened in the level above is in evidence. At the 23d level a stope 20 ft. high and about 75 ft. long has been cut the full width of the vein, which averages about 12 ft.; the mineralization is equal to any yet found on this formation.

Oscoda—No. 4 shaft of the North Kearsarge branch of this property will soon be in shape to begin producing. The surface equipment will be ready as soon as the underground openings are sufficient to maintain steady shipments. The shaft hoise is ready for sheathing and the machinery is being erected at the hoisting and compressor plants. The shaft will command the ground tributary to the southern boundaries of the Ahmeek and Allouez properties, and is opening a most encouraging copper-bearing belt. This tract carries the outcropping of the Kearsarge lode.

Keweenaw—The lower levels of the company's shaft are revealing a much better grade of rock. At the 11th level a fissure vein was encountered, and drifting on this is under way with a fine copper showing.

Phoenix Mill—The plant continues operating one shift a day; with the improve-

ments inaugurated some time ago more satisfactory results are obtained.

Mass Consolidated—At the close of the year 1907 the company had net cash assets, over and above all indebtedness, of \$94,000. This has been reduced by about \$35,000 as the result of operations in 1908. The average monthly loss during 1908 was, therefore, \$3,000, although in the months of November and December the mine made a little money over and above all expenses. Of the small deficit in 1908 at least \$25,000 represents the cost of diamond-drill explorations. The company will not be in the immediate need of funds, and if the metal market should advance from its present level the mine should be able to work out a small net profit. At one time during the year the company was carrying about a six months' supply of copper, or 750,000 lb., against which it was borrowing \$100,000. At the present time this supply has been reduced to about 600,000 lb., while the borrowings have been reduced from \$100,000 to \$65,000. The present output is about 150,000 lb. of refined copper monthly.

Montana

BUTTE DISTRICT

Butte & London—The annual meeting of stockholders will be held at Butte on Jan. 19. Directors will be elected for the present year and the policy of the company will be determined.

JEFFERSON COUNTY

Butte & Corbin Company—At a meeting of directors held at Butte this week, Lee Bever was elected president, Lee Williams, vice-president, and J. P. Fitzpatrick, secretary and treasurer. The company's property is located in the Corbin district and has been developed by a tunnel 300 ft. long.

BROADWATER COUNTY

Keating Gold Mining Company—At a meeting of stockholders, J. B. Roote, James A. McKee, C. C. Willis, W. R. Kirk, and C. S. Blackiston were elected directors for the year. Mr. Roote was elected president to succeed A. P. Nipgen, resigned, and Mr. McKee was elected vice-president. C. C. Willis will be assistant superintendent. The management states that since the commencement of operations by the company last July the gross smelter returns on ore shipped has amounted to \$82,542.

CARBON COUNTY

Bear Creek District—Since the sale of a large tract of coal lands to Thomas Ryan two weeks ago there has been much activity in the location of coal lands in the district. Within the last 10 days all of sections 22 and 26, and the greater part of sections 29, 30, 31, 32, 34, 35 and 36 have been located.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Consolidated Red Top Lease—This lease on the Red Top claim of the Goldfield Consolidated company, has developed some high-grade ore in the south drift on 225-ft. level. The orebody, which was only a narrow talc seam where first found, has gradually increased to a width of 18 in.; the ore is a sulphide, showing considerable rusty gold. Eighty sacks of high-grade ore have been saved.

Daisy Florence Lease—This lease, operated by Mitchell & Fairfield, recently encountered ore in a raise from the 315-ft. level. Returns from the first shipment of 30 tons gave a value of \$75 per ton. The raise is now 25 ft. above the floor of the level and shows 4 ft. of quartz which assays \$40 per ton after the high-grade ore has been sorted out.

Goldfield Kewonas—The vertical shaft is now 470 ft. deep, and at that depth a crosscut is being run to connect with the old incline shaft, which, although good shipping ore was found, had to be abandoned at a depth of 500 ft., because of a heavy flow of water. The crosscut, which is now 75 ft. long, will be continued 275 ft. farther; at that point a raise of 115 ft. will be driven to connect with the old shaft.

Kewonas Extension Mining Company—This company, leasing on the north end of the Kewonas No. 2 claim, is sinking with a view of cutting the Hazel vein, which should pass through its ground. The shaft is now 360 ft. deep.

Combined Mining and Leasing Company—The officers of this company have secured a new 18-months' lease on their old leasehold on the Velvet claim of the Goldfield Merger Company; this dates from Jan. 1, 1909. A contract for 200 ft. of crosscutting has been let.

Hazel Goldfield—The shaft, which cut an orebody at a depth of 720 ft., is being carried down on the vein. It is now 740 ft. deep, being the deepest lease shaft in this district. The orebody, which in places is 75 ft. wide, is of milling \$8 grade, with bunches of high-grade ore in it that assays from \$25 to \$300 per ton. This is thought to be a continuation of the Red Top vein.

Grizzly Bear Lease—Work on this lease, which is on the Grizzly Bear claim of the Consolidated company, has been resumed, and the shaft, now 200 ft. deep, is being sunk at the rate of 3 ft. per day. A six-months' extension has been granted the lessees provided that the shaft is 800 ft. deep by Feb. 1, 1910.

Kansas City Goldfield Leasing Company—This company, which is operating the old Ricker lease on the Velvet claim, recently developed ore in a winze; this ore improves with depth; 10 tons are ready for shipment.

Goldfield Consolidated—The new 600-

ton mill commenced operations Dec. 26, and is dropping 60 stamps, which number will be gradually increased by the end of January to the full capacity of 100 stamps.

ESMERALDA COUNTY—RAWHIDE

Nugent Lease—The shaft is 100 ft. deep; on the 100-ft. level several crosscuts have been driven at this lease on the Coalition property. In one of the drifts a north-south shoot of ore was struck that assayed high in silver; the silver was found mostly in the talc which is about 2 ft. wide; some of this talc ore went as high as \$700 a ton. On this lease there is another vein about 7 ft. wide that will average \$16 per ton.

Victor Lease—On the 100-ft. level one of the walls of the vein is very well defined; the ore on this level is about 4 ft. wide, 1 ft. of it running several hundred dollars in gold to the ton. On the 200-ft. level the vein widens to 15 ft., and is nearly all quartz; the footwall is porphyry as on the 100-ft. level. The ore from a width of 15 ft. across the vein assays about \$25 a ton; the 8 in. next to the walls is very rich. This lease is on the main vein of the camp; apparently, this vein is also the best carrier of gold in the district.

Truitt Lease—The shaft at this lease on Hooligan hill is 70 ft. deep. On the 70-ft. level several long drifts have been driven and much ore has been mined. From this level a winze 100 ft. deep has been sunk following the ore. Most of the mining now being done is on this, the 170-ft. level. Machine drills are used, and shipping ore is being taken out. The ore is barren looking, but much brecciated, and the seams are filled with oxidized material carrying gold; the rock as broken assays about \$50 to the ton. The vein matter for a width of 40 ft. will probably pay to mill. The Truitt lease has shipped 700 tons.

Miller Lease—This lease is on Hooligan hill between the Victor and the Truitt leases, and is the highest upon the hill. The first level is the 65-ft.; on this level the incline shaft is connected with the vertical shaft which is 165 ft. deep. The incline shaft follows the ore, and is continued to the 165-ft. level, the deepest in the mine. The orebody in the incline shaft seems to be the main one, as from it all the shipments have been made. On the 165-ft. level drifts have been run in several directions, and in each one milling ore has been found that assays from \$12 to \$20 a ton. The main oreshoot still continues in the bottom of the incline shaft and is about 6 ft. wide. The formation is the same in this lease as in the Truitt, but the vein is more regular and better defined, more quartz being found on the lower levels.

Brodshaw Lease—In the prospect shaft, 50 ft. deep, at this lease on the east side of Ballon hill a rich vein of talc has been found. The owners have taken out

some ore assaying as high as \$600 per ton.

Murray Lease—A rich strike has been made on the 200-ft. level of this lease on the Rawhide Consolidated property. The Murray 10-stamp mill which is being built by the Allis-Chalmers Company is rapidly nearing completion; it is to be ready by Feb. 15. The stamps weigh 1250 lb. each.

St. Ives Lease—A rich strike was recently made at this lease on Ballon hill by A. A. Codd and associates. On Jan. 3 the lease began shipping ore from the new strike.

EUREKA COUNTY—EUREKA

Windfall—J. J. Jones, of Goldfield, and associates who purchased this property last October for \$200,000 are sinking a vertical, two-compartment shaft; this shaft is now 175 ft. deep. The company plans to build a 100-ton cyanide mill.

HUMBOLDT COUNTY—SEVEN TROUGHS

Wihuja Lease—Stoping is being done on the 265-ft. level, and sinking has been resumed from the 365-ft. point at which depth on account of a large flow of water sinking was stopped. The last lot of 150 tons from this lease returned \$175 per ton.

Mazuma Hills—The shaft is being sunk, and considerable drifting is being done. The mill will be started this week.

English George Lease—All of the machinery for the Huntington mill to be erected on this lease, has reached Mazuma and work of construction is being rapidly pushed.

NYE COUNTY—TONOPAH

Production for the week ending Dec. 26 was 5183 tons having an estimated value of \$129,575. The West End mined 150 tons; Tonopah Mining Company, 2950; Midway, 100; Montana Tonopah, 658; MacNamara, 325; Jim Butler, 300; Belmont, 700 tons.

Belmont—During the week ending Dec. 26, 130 feet of new ground was broken. Considerable development work is still being done in the upper levels, but this week most of the development was done on the 1000- and 1100-ft. levels.

West End—Development work is quite satisfactory; while stoping is being carried on in several places, no attempt is being made to produce a large tonnage. The week's work showed a marked improvement in the paystreak on the 400-ft. level.

NYE COUNTY—BULLFROG

Pioneer—The rich strike in this mine at Springdale, ten miles north of Bullfrog, is causing considerable excitement. The orebody which is 12 ft. wide is of good grade. The gold is rusty and is quite evenly disseminated throughout the quartz. The first shipment to Salt Lake City was made Jan. 1. The mine is now employing 40 men.

NYE COUNTY—BERLIN

Blue Bell—At this property only sufficient ore is being taken out to supply 20 stamps. This ore comes from a winze on the 125-ft. level. Work is being rushed on the 400-ft. level in order to get beneath this orebody; then the 30-stamp mill will be run at full capacity. On the 125-ft. level the vein varies from 4 to 15 ft. in width and is of good milling grade. The mill clean-up for November amounted to about \$10,000 in bullion and \$15,000 in concentrates. This company also owns the Downieville mine, 15 miles to the west; at present the company is negotiating the sale of that mine.

NYE COUNTY—HELENA

Broken Hills—Three hoists are now operating on this property, and two more, to be used on leases, are in transit. The last carload, consisting of 600 sacks, that was sent to the Western Ore Purchasing Company at Millers, gave returns of \$122 per ton.

WHITE PINE COUNTY

Giroux—Control of this company has been secured by Cole & Ryan, which explains the recent rise in the stock.

Cumberland-Ely—A syndicate has been formed which has taken from the treasury of the Nevada Consolidated Copper Company the remaining 125,000 shares of Cumberland-Ely stock at not far from the present market price. The Nevada Consolidated sold the shares in order to finance an extension of the Steptoe smelter and mill. The Nevada Consolidated company originally owned 200,000 shares of Cumberland-Ely stock acquired in part payment when that company sold the Cumberland-Ely a one-half interest in the Steptoe reduction works for \$3,000,000.

New Mexico

GRANT COUNTY—SYLVANITE

Sylvanite now has a full fledged post-office. Edwin J. Clark, one of the locators of the camp, has been appointed postmaster.

Wood Mine—Colorado capitalists headed by Jesse H. Waters, of Colorado Springs, president of the Midland Terminal and Florence & Cripple Creek railroads, have secured from the Pierson Brothers and W. E. Irwin a working bond and option on the Wood mine. Besides a substantial cash payment the vendors will receive shares in the company that is to be incorporated. Mr. Waters and associates also purchased the Ruth group of three claims on the eastern extension of the Clemmie vein. I. J. Russel, who sampled the mine for the purchasers, will have charge of the operations on both properties. A force of miners has been put to work.

Buchanan Group—Pierson Brothers & Irwin have bonded a group of six claims belonging to R. B. Buchanan, about a mile north of the Wood mine, for \$40,000. Work of developing the new property will begin at once.

North Carolina

MONTGOMERY COUNTY

Iola Gold Mine—This mine has been sold by order of court to Capt. William Fleming, Waldorf-Astoria hotel, New York, for \$50,000 cash. Capt. Fleming is well known as a director in several successful mines.

ROWAN COUNTY

Gold Hill Copper Mines—The sale of this mine in bankruptcy is ordered to take place Jan. 27. The property includes the large plant and several hundred acres of land. This is a well-known curb stock.

Tennessee

PUTNAM COUNTY

Georgia-Tennessee Phosphate Company—This company is now constructing a narrow-gage railway, half a mile long from its mines at Boma to a connection with the Tennessee Central Railroad. It is also putting in two 100-h.p. Walsh & Weidner, internal-fired boilers, and a hoisting engine, and will install a crusher with capacity of 500 tons per day.

Utah

BEAVER COUNTY

Newhouse Mines and Smelters—This company has a floating debt of \$144,000. The company is producing 600,000 lb. of copper a month at a net profit of \$20,000. New tables and machinery are being installed at the mill so as to increase the yearly output of the company to 12,000,000 lb. of copper.

Beaver Mine—The drift on the 700-ft. level has passed through the first ore-shoot and now a raise is being driven in it. The 700-ft. level is being driven farther east, with indications of another ore-shoot nearby.

SALT LAKE COUNTY—ALTA

Utah Mines Coalition Company—This company has filed articles of incorporation. The headquarters of the company are at Salt Lake. The capital is \$1,250,000, in shares of \$2.50 each, 250,000 shares remaining in the treasury. The officers are: Duncan MacVichie, president; James B. Risque, vice-president; Roland H. Strickland, secretary; Louis H. Farnsworth, treasurer. The property of the old Black Bess company and other patented claims near the head of Big and Little Cottonwood cañons have been taken over by the new company. There are four known veins in the property. One of these veins

has been developed to a depth of 350 ft. by shaft workings. The new company plans to drive an adit on the most northerly of the veins and to crosscut from this adit to the other lodes. This adit will be driven at a depth of 1000 ft. below the collar of the present shaft; its portal will be 75 feet above the level of Lake Solitude. From there a good wagon road extends to the railroad.

SALT LAKE COUNTY—BINGHAM

Bingham-Butte—Recently at a special meeting of the stockholders a bond issue of \$200,000 was authorized. This issue will be secured by 400,000 shares of treasury stock and a mortgage on the property. Developments at the mine are promising. Part of the money raised by this issue is to be expended in purchasing nearby property.

SUMMIT COUNTY

Shipments—Shipments from the Park City mines amounted to 2168½ tons of lead ore during the week ending Dec. 20. The Daly-West shipped 750 tons; Silver King, 1069; Daly-Judge, 289½ tons. During the week ending Jan. 3 the Park City mines shipped 1769 tons of lead ore and 138 tons of zinc concentrates; the last from the Daly-Judge. The Silver King shipped 770 tons; Daly-West, 575; Daly-Judge, 279½; American Flag, 144½ tons.

Little Bell—The work has been resumed. At first this will be confined to the 300-ft. level as that is connected with the Quincy shaft of the Daly-West property through which the mine will be worked, and at present no attempt will be made to operate through the winze. Ed. Talbot, of the Daly-West mine, is in charge of the work at the Little Bell.

Silver King Coalition Company—One of the lawyers for this company is reported to have stated that the Silver King Coalition has refused and will refuse to deliver to F. A. Heinze ore claimed under the contract alleged to have been made several months ago. In the meantime the Heinze interests are putting the Majestic smelter at Milford in shape for operation.

West Virginia

MCDOWELL COUNTY

Pocahontas Consolidated—A second explosion on Jan. 12 wrecked the Lick Branch coal mine of this company at Switchback, killing 105 men. The mine had just been examined and declared safe by the State inspectors, and a force of 200 men had been put to work for the first time after the explosion of Dec. 28, when 50 miners lost their lives.

Philippine Islands

Benguet Consolidated Mining Company—This company's statement for October shows a production of 186 oz. gold and

150 oz. cyanide bullion. Work was stopped 10 days by a typhoon which caused a landslide breaking the flume and stopping the supply of water.

Paracale Gold Dredging Company—This company reports 630 oz. gold saved during the month of October.

Canada

ONTARIO-COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ending Jan. 2 were as follows. Coniagas, 53,060 lb.; City of Cobalt, 67,000; Kerr Lake, 61,000; La Rose, 406,510; McKinley-Darragh, 114,000; Nipissing, 258,210; O'Brien, 124,325; Temiskaming, 120,000; Trethewey, 240,000; Total 1,454,195 pounds.

Chambers-Ferland—At 120 ft. in No. 1 shaft a marked improvement has occurred in the vein, which shows at this point 18 in. of high-grade ore. In the west crosscut from No. 2 shaft at a distance of 219 ft. a deposit of low-grade ore showing calcite, niccolite and galena was encountered 8 ft. in width.

Little Nipissing—On the Peterson Lake lease a crosscut is being driven at 150 ft. toward the main vein. When this is reached drifting will be carried 50 ft. along the vein to cut a rich cross-vein which yielded rich ore at the 100-ft. level.

Rochester—The main shaft is down 170 ft. but progress in sinking has latterly been slow owing to water. This difficulty has now been overcome and the work is being pushed.

Silver Queen—Underground development is being undertaken on a large scale. Sixty-five men and 7 drills are at work on the 75- and 150-ft. levels, and about 3500 ft. of drifting and crosscutting have already been done. A new shaft is being put down to the south of the main workings and is now down 75 ft. A sump a few feet in depth will be sunk and a station cut. Several veins giving good indications will be worked from this shaft.

ONTARIO-MONTREAL RIVER DISTRICT

Otisse—A rich find is reported at a depth of 30 ft., where a surface vein has widened to between 12 and 18 in. and is yielding high-grade ore. A carload of ore is awaiting shipment.

Mexico

CHIHUAHUA

Tecolotes Y Anexas—The mill at Santa Barbara is treating 800 tons daily. About 40,000 tons of zinc middlings are impounded about the mill and a plant for the treatment of this product is planned. Ore bins of 5000 tons capacity have been constructed at the mines, which will be connected with the mill by an aerial tram to be in operation May 10. The picking

belts will be removed to the mines and only sorted ore sent to the mill.

Las Cuadras—This property, three miles north of Santa Barbara has been taken over by C. M. Dobson, the former manager. The work of retimbering the main shaft has proceeded below the 400-ft. level, and trial shipments from the dumps to the smelter have been begun.

Rio Plata—The cyanide plant near Guazapares is expected to be ready for operation in February.

Gibraltar—A strike of rich ore is reported in this property in the Naica camp.

JALISCO

Jalisco Exploration—Ore carrying gold and silver has been encountered east of the Cinco Minas in the Hostotipaquillo district. Thomas Henderson is in charge of operations.

MEXICO

Olvidado—This mine, at Zacualpan has shipped its third carload of high-grade ore to Toluca. The property is new and was opened six months ago. The ore shipped is the result of development work only.

Seguranza—This company, of San Luis Potosi, has begun the erection of a new 100-ton cyanide plant on the property at Zacualpan. The plant is to be completed within six months. Electric power is transmitted from Temascaltepec. The Seguranza is the old Coronas mine. Geo. A. Waddell, San Luis Potosi, is manager.

Carboncillo—A rich strike is reported from this property in the Zacualpan district.

OAXACA

Tehuantepec Silver Mines Company—This company, which owns the San Francisco mine, in Taviche has applied for a concession for the use of the water of the Arroyo De Exegee in Ocotlan. The power is to be used to operate a proposed stamp mill.

San Carlos—This property, at Taviche, which has been operating with a reduced force for the last seven months, resumed with a full complement of men on Jan. 10. Sinking and lateral development has been resumed.

Santa Catarina—The first clean-up from the new cyanide plant has been made with good results. Enough tailings have been stacked to keep the plant running many months.

Mascota—The Piocha adit has cut the principal vein on this property in the San Carlos district, after driving through 125 meters of diorite. The vein is large, mostly oxidized and of low grade, but carrying rich pockets.

SONORA

Greene-Canaan—The copper production for the month of December amounted to 3,450,000 pounds.

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, Jan. 13—The coal trade in the West seems to have relapsed into dullness for a time, the little spurt of the last half of December having passed over for the present. Continued mild weather has had its influence in the cities and the demand for steam coal seems to have dropped off for the time. In Indiana and Illinois most of the mines are working only half time, and in Ohio the condition is hardly as good as that. Operators are hopeful, however, that the steam-coal demand will shortly improve. It must do so as business revives, since very few manufacturers are carrying large stocks.

The Seaboard bituminous trade is quiet. No business is doing through New England territory, and in New York and Pennsylvania there seems to be a lull in buying.

The anthracite trade is also dull with very little doing at the principal centers. The companies, however, are keeping up shipments steadily. There has been abundant rain throughout eastern Pennsylvania, so that the reservoirs are filling up, and delays caused at the mines by short water supply are gradually disappearing.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to Jan. 4, 1908 and Jan. 2, 1909, in short tons:

	1908.	1909.	Changes.
Anthracite.....	24,707	477	D. 24,230
Bituminous.....	362,376	127,031	D. 235,362
Coke.....	69,845	63,128	D. 6,717
Total.....	456,928	190,619	D. 266,309

Daily average was 114,232 tons in 1908, and 95,310 tons this year.

Anthracite coal shipments from Buffalo by Lake for the full season were 3,297,460 long tons in 1907, and 3,249,207 in 1908; a decrease of 48,253 tons.

Anthracite shipments in December again showed an increase, the total being 5,827,938 long tons, an increase of 484,461 tons over December, 1907. For the 12 months ended Dec. 31 the shipments were, in long tons:

	1907.	1908.	Changes.
Reading.....	14,018,795	12,678,883	D. 1,489,912
Lehigh Valley.....	11,532,265	10,772,040	D. 760,215
N. J. Central.....	8,714,113	8,458,425	D. 255,688
Lackawanna.....	10,267,419	10,098,697	D. 168,722
Del. & Hudson.....	6,562,768	6,461,666	D. 101,102
Pennsylvania.....	6,203,271	6,019,457	D. 183,814
Erie.....	7,151,683	7,450,175	I. 298,492
N. Y., Ont. & West.	2,889,989	2,798,071	I. 109,582
Total.....	67,109,393	64,665,014	D. 2,444,379

Two companies showed increases in 1908—the Erie and the New York, Ontario & Western. The largest proportional decrease was on the Reading; the smallest on the Delaware, Lackawanna & Western. The total decrease was 3.6 per cent.

The coal tonnage originating on the lines of the Pennsylvania railroad east of Pittsburgh and Erie for the full year was, in short tons:

	1907.	1908.	Changes.
Anthracite.....	5,691,983	5,216,075	D. 475,908
Bituminous.....	39,718,356	34,246,864	D. 5,471,492
Coke.....	13,047,593	7,239,866	D. 5,745,727
Total.....	68,457,932	46,761,805	D. 21,696,127

Decrease in anthracite, 8.4 per cent.; in bituminous, 13.8; in coke, 44.1; in the total tonnage, 20 per cent.

Receipts of domestic coal at Boston for the full year, reported by Chamber of Commerce:

	1907.	1908.	Changes.
Anthracite.....	2,053,328	1,776,401	D. 276,927
Bituminous.....	3,184,964	3,302,929	I. 117,965
Total.....	5,238,292	5,079,330	D. 158,962

Receipts of foreign coal—chiefly from Nova Scotia—in 1908 were about 360,000 tons.

Coal tonnage Chesapeake & Ohio Railway, five months, from July 1 to Nov. 30, short tons:

	Coal.	Coke.	Total.
New River.....	2,752,948	88,566	2,841,514
Canawha.....	2,153,707	12,354	2,146,721
Kentucky.....	148,013		148,013
Connecting Lines.....	108,294	26,614	135,108
Total.....	5,143,022	128,334	5,271,366
Total, 1907.....	5,133,664	195,339	6,329,003

Deliveries in 1908 were: To points west of mines, 2,766,247 tons coal and 76,271 coke; points east, 626,928 tons coal and 42,063 coke; tidewater, 1,805,757 tons coal; anthracite to line points, 4088 tons.

New York

ANTHRACITE

Jan. 13—The hard-coal market continues very dull. The few frosty days of last week gave some hope of improvement, but the cold did not last long enough to give any special impetus to the trade. Supplies continue very good, both of domestic and of small steam sizes. In fact it is reported that the anthracite companies are storing considerable quantities in their yards in New Jersey and Pennsylvania, to provide against any possible shortage next spring.

Schedule prices are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No.

2 or rice, \$1.60@1.2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS

It is always expected at this season that local trade will be light, as very little business is usually done in the first week in January. This year, however, it is unusually dull, coming on top of a long quiet period. The far East is taking no coal just now and the Sound very little. New York harbor business is practically dead for the present. In the absence of business, prices may be said to hold at \$2.45@2.65, New York harbor, for good grades of Clearfield. All-rail business is moderate. Cars are plentiful, but transportation a little slow.

In the Coastwise trade little is doing, but vessels are also scarce and rates are about the same. From Philadelphia, we quote: Boston and Portland, 75c.; Salem, Lynn and Bath, 85c.; Newburyport, 95c.; Portsmouth, 80c.; Providence, New Bedford and the Sound, 60c@65c. per ton.

Birmingham

Jan. 11—Coal operations in Alabama promise to be steady for some time. The distribution of convicts among the coal companies will bring about some development. Heretofore but two coal companies have been using convict labor, the Tennessee and the Sloss-Sheffield. The Pratt Consolidated Coal Company and the Bessemer Land and Improvement Company are also using that labor now. There is considerable free labor still to be had for the mine work in this State, and it is being taken up more and more. The demand for coal is steadily improving. The quotations are holding their own. The larger consumers of coal in the Southern territory, the railroads in particular, are requiring more coal every month.

Much coke is being used in this district. The Tennessee company has considerable coke stacked up in various parts of the district, but not too much when it is proposed a little later on to start up several furnaces.

Chicago

Jan. 12—Cold weather for the last five days has increased materially the demand for domestic coals, throughout Chicago territory. There is still much coal in the bins of retailers and consumers, however, owing to the mild weather of December and a lively market has not yet appeared. It does not seem likely to appear for sev-

eral days, unless the extreme cold of the Northwest, where the demand is active, should continue throughout the upper Mississippi valley. Conditions at present, however, are decidedly better for wholesalers than they have been for several weeks.

The weather, both by increasing demand and checking the movement of incoming supplies, has done away with most of the demurrage selling that has persistently shaded prices on western lump, smokeless and Hocking for the last two weeks. Illinois and Indiana coals bring: Lump and egg, \$2@2.65; run-of-mine, \$1.65@1.75, and screenings, \$1.40@1.60. Smokeless is still in large supply for the demand, for the lower-priced kind, though Pocahontas and New River hold up well toward the standard prices of \$3.65 for lump and \$3.15 for run-of-mine. Hocking has a good demand, but large shipments, with standard price—\$3.15 for 1¼-in. lump—cut 25c. in some sales. Youghiogheny is quiet at \$3 for steam and \$3.15 for gas ¾-in. lump.

Anthracite has shown activity for the first time, with cold weather, and all sizes are in good demand in city and country, with supplies large.

Cleveland

Jan. 12.—The coal market is dull, owing to the mild weather, which still limits domestic demand, and to an apparent falling off in the demand for steam coal. Lump and run-of-mine from Ohio districts are exceedingly quiet. The recent activity in slack has subsided for the most part. Prices, however, have not changed.

Indianapolis

Jan. 11.—Indiana coal operators say with confidence that the coal-mining industry will take on an improved condition from this time on. They base this on the reports of the resumption of large coal-consuming mills and the certainty of colder weather. The closing month of the year was light in tonnage output, but operators believe the new year will open up good demand.

The indications for an improvement in the Block Coal district are better now than for some time. The season up to this time has been the worst in the history of the district, due largely to the mild weather. The average of work has been about half-time, while in some mines it has been even less. A few mines in this district have worked almost every day, but these are mines that were fortunate in getting large municipal contracts in Chicago and other cities.

The Mine Workers' legislative committee has prepared a bill to be introduced in the Legislature covering apprenticeship of miners. The bill provides that anyone starting work in a mine should first be

employed under the direction of a practical miner for two years, to become familiar with the machinery and the condition of the mines. This is similar to the provisions of the Pennsylvania law.

Pittsburg

Jan. 12.—The high water in the past 10 days made the rivers navigable and resulted in the shipment of between 3,000,000 and 4,000,000 bush. to Cincinnati and other lower river points. Large operators have reaffirmed the price for both river and rail coal on the basis of \$1.15 for mine-run. Slack is strong at 75c. All the mines in the Pittsburg district are being operated at about 60 per cent. of capacity.

Connellsville Coke—The market has been easier, prompt coke being offered at 15c. or more concession from contract prices, which remain at \$2 for furnace and \$2.25@2.40 for foundry. The *Courier* reports production in the Connellsville region for the week at 148,710 tons, and in the lower field at 103,348; a total of 252,058 tons. Shipments for the week aggregated 6944 cars distributed as follows: To Pittsburg district, 3115 cars; to points west of Pittsburg, 3171 cars; to points east of Connellsville, 658 cars.

Foreign Coal Trade

United States Coal Imports—Imports of coal and coke into the United States, 11 months ended Nov. 30, long tons:

	1907.	1908.	Changes.
Anthracite.....	6,901	16,483	I. 9,582
Bituminous.....	1,890,754	1,378,211	D. 512,543
Total coal.....	1,897,655	1,394,694	D. 502,961
Coke.....	121,963	119,647	D. 2,316

In 1908, Canada contributed 1,017,746 tons of coal and nearly all the coke; Australia, 310,875 tons of coal. Imports are chiefly on the Pacific coast.

United States Coal Exports—Exports of coal and coke from the United States, with coal sold to steamships in foreign trade, 11 months ended Nov. 30, long tons:

	1907.	1908.	Changes.
Anthracite.....	2,553,901	2,579,865	I. 25,964
Bituminous.....	9,991,815	8,371,046	D. 1,220,769
Total exports.....	12,145,716	10,950,911	D. 1,194,805
Steamer coal.....	5,250,173	5,490,720	I. 240,547
Total.....	17,395,889	16,441,631	D. 954,258
Coke.....	813,914	546,019	D. 267,896

In 1908, Canada took 2,549,280 tons anthracite and 6,664,677 tons bituminous; a total of 8,604,066 tons, or 78.6 per cent. of the total.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on Jan. 2: Best Welsh steam, \$3.48; second, \$3.36; thirds, \$3.24; dry coals, \$3.60; best Monmouthshire, \$3.18; seconds, \$3.06; best small steam, \$2.04; seconds, \$1.74. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, Jan. 13—The first two weeks of 1909 in the iron and steel trades have been marked by almost absolute dullness. Buyers probably are not yet through taking stock and are still uncertain as to the demand for finished products. At any rate there is evidence of a waiting market; the only question is how long this may last.

In pig iron there is considerable inquiry, but it looks as if most of this was of a tentative character; so far it has resulted in few actual sales. Foundry iron is selling in small lots and orders are not numerous. In steel pig there is nothing doing with outside furnaces. There are inquiries for some basic iron, but no actual sales of importance.

In finished material conditions are also quiet. Even structural steel remains dull for the present, no new contracts of any considerable size having been closed, although there are many projects under discussion and some have approached the stage of bids. The railroads are not yet ordering rails freely. The Pennsylvania order was expected to break the ice, but others are not following as yet.

In export trade it is reported that considerable business has been done in sheets, wire and wire products. There has been some talk of export orders for rails, but no actual business is reported. It may be noted that British makers have recently taken some large orders for South America which it was thought would be captured for this country.

Pig-iron Production—The reports from the blast furnaces, collected by the *Iron Age*, show that on Jan. 1 there were 220 stacks in blast, having an aggregate weekly capacity of 400,000 tons of pig iron; an increase of 20,000 tons over Dec. 1. Making allowance for the charcoal furnaces, we begin 1909 with production at the rate of 21,000,000 tons yearly.

Baltimore

Jan. 11.—Exports for the first week in the year were light. The only important item was 4,534,800 lb. steel billets to Liverpool.

Birmingham

Jan. 11.—Alabama manufacturers of pig iron are receiving some orders, though the buying this year has not yet opened up strong. The quotations remain firm at \$13 per ton, No. 2 foundry, though 50c. per ton better has been asked. Some of the larger consumers have been making inquiry in the Birmingham territory for iron, ostensibly for second-quarter use and the sale of some 20,000 tons of iron, for eastern delivery, is announced. The cast-iron pipe people are preparing to lay in supplies, but for some reasons are not rushing the market.

The make is picking up a little in this section, though no furnaces were reported as going in blast during the past few days. The authoritative figures given out are to the effect that Alabama produced during 1908 something like 1,410,500 tons of iron, about 200,000 tons less than in 1907. The last month of the year was the best, the production going up to 146,803 tons against 86,036 tons in January.

At Ensley the Tennessee Coal, Iron and Railroad Company has acquired a large additional tract of land, and it is understood that structural iron and steel plants will be erected. The steel mill is in better operation now than it has been in some time. Efforts are being made to fill orders on hand, especially in steel rails.

Chicago

Jan. 12—The iron market continues quiet, purchases of pig iron and of finished materials being small in tonnage and not increasing materially in number from the holiday season. Prices remain firm, No. 2 Northern being sold at \$17.50@18, and No. 2 Southern at \$13@13.50 Birmingham (\$17.35@17.85 Chicago) on first-half business. The demand for iron is scattered, some melters continuing to buy on short-time delivery, and others contracting for deliveries six months hence on a carefully conservative basis. Structural material, sheets, plates, bars and other iron and steel products are lagging in sales.

There are no evidences of weakness in the market and the quietness in pig iron is in part due to inventories by foundries and the making of changes which naturally come with the opening of the new year. Furnace agents do not display anxiety to hasten sales and profess faith in the gradual resumption of business.

Coke is somewhat dull and there is a tendency to ship in more than the market will stand. The price of coke remains \$4.90@5 for the best Connellsville.

Cleveland

Jan. 12—The markets have been dull since the opening of the year, and little new business in iron and steel is noted in this territory. There is some inquiry for pig iron, but it has not resulted so far in orders of any importance, sales having been made chiefly in small lots.

Some increase is reported in shipments of ore from docks to furnaces. No action has been taken yet on the question of ore prices for the coming season.

Philadelphia

Jan. 13—Pipe iron and basic iron are engaging the attention of the market, but with only a moderate amount of business transacted during the week in this territory. While most consumers have only small quantities of iron in their yards, and

not very much under contract for delivery, there is very little disposition to buy. Local makers are not receiving inquiries. Buyers who are accustomed to order far ahead are inclined to wait to see what is to be the probable outcome of tariff revision. Makers are not pushing iron on the market, and are renewing small contracts on former terms.

Steel Billets—No sales are reported. There is a rumor that quotations have been shaded, but no recent transaction corroborates them.

Bars—Buyers of bars are occasionally ordering enough to run them into April. Prices continue low.

Structural Material—The business is disappointing. Negotiations which started in December have not matured. Mill people say there is a general disposition to hold off. A lower level of quotations appear inevitable on large contracts.

Scrap—Heavy steel scrap is snapped up wherever it is to be had, and at good prices. Some sales are being made daily of other kinds, but scrap dealers are obliged to hold the bulk of their incoming supplies, which they are confident they can get rid of in a few weeks at a good profit.

Pittsburg

Jan. 12—The iron and steel market seems to be reaching an interesting stage, as in some directions there is a heavy increase in the buying of finished steel products, while in others there has appeared severe cutting by some producers which, if continued, may force reductions in some products.

The most satisfactory accounts come from the wire trade, a prominent producer in this line reporting its business this week as at the heaviest rate for 14 months, and well distributed among the different lines of wire goods. As the wire trade touches more nearly the ultimate consumers, and the goods cover a wide range of consumers and practically the entire country, it is natural that the first evidences of reviving trade should come in this line, so that the showing is taken as foreshadowing a general improvement in the iron and steel trade as the new year progresses.

Pig Iron—There has been some improvement in inquiry, but sales have been very light. Furnaces are holding to prices firmly, although in some cases they are piling some iron. It develops that the purchases of basic by the Pittsburg Steel Company last month were larger than was then supposed, amounting to close to 20,000 tons, and covering the company for this quarter, with the iron it receives on the term contract made recently with the Penn Iron and Coal Company. The price paid was substantially \$15.50, Valley, although a large part of the tonnage went through middlemen by the medium of *coke* deals. Another interest has been in

the market for basic, and developed prices of \$15.50, but latest reports are that it has not bought. Bessemer remains at \$16.50, Valley, but is extremely quiet and the market is not strong. Foundry iron is held at \$15.50@16, Valley, a number of furnaces not being willing to sell at the lower price. Forge is quoted at \$14.50 Valley. Prices delivered Pittsburg are 90c. higher.

Steel—Shipments of billets and sheet-bars are up to the average maintained in the past two or three months, but are almost altogether on old contracts, there being scarcely and new buying. Prices remain on the basis of \$25 for billets and \$27.50 for sheet-bars, Pittsburg. Plates are nominally 1.60c., but are being shaded, particularly on the narrower sizes.

Sheets—Business in sheet is picking up and mill operations are maintained on about the same basis as last week. Black sheets are 2.50c. and galvanized sheets 3.55c., 28 gage, f.o.b. Pittsburg.

Foreign Trade in Iron and Steel

Iron and Steel Exports—Exports of iron and steel, including machinery, from the United States for the 11 months ended Nov. 30, are valued by the Bureau of Statistics of the Department of Commerce and Labor at \$182,068,912 in 1907, and \$138,881,761 in 1908; a decrease of \$43,187,151, or 23.7 per cent. Leading items of export, in long tons:

	1907.	1908.	Changes.
Pig Iron.....	70,599	41,964	D. 28,635
Billets, ingots & blooms	74,831	104,284	I. 29,453
Bars.....	92,638	61,251	D. 31,387
Rails.....	318,143	186,467	D. 131,676
Sheets and plates.....	113,544	93,560	D. 19,984
Structural steel.....	129,041	106,943	D. 22,098
Wire.....	147,597	124,214	D. 23,383
Nails and spikes.....	53,493	34,130	D. 19,363

Considerable decreases are shown in all items except billets, ingots and blooms.

Iron and Steel Imports—Imports of iron and steel, including machinery, into the United States for the 11 months ended Nov. 30, were valued at \$36,740,291 in 1907, and \$18,247,668 in 1908; a decrease of \$18,492,623, or 50.3 per cent. Leading items of import, in long tons:

	1907.	1908.	Changes.
Pig Iron.....	478,448	81,872	D. 396,576
Scrap.....	26,516	4,029	D. 22,487
Ingots, blooms, etc.....	18,441	9,060	D. 9,382
Bars.....	36,077	18,565	D. 17,512
Wire-rod.....	15,807	10,556	D. 5,251
Tinplates.....	56,231	6,015	D. 216

There were considerable decreases in all items except tinplates, in which there was little change.

Iron Ore Movement—Exports and imports of iron ore in the United States for the 11 months ended Nov. 30 are reported as follows, in long tons:

	1907.	1908.	Changes.
Exports.....	261,869	301,342	I. 39,473
Imports.....	1,149,319	652,559	D. 496,760

Imports of manganese ore for the 11 months, 188,526 tons in 1907, and 170,662 in 1908; a decrease of 17,864 tons.

Metal Markets

New York, Jan. 13.—The metal markets generally have not been strong, and the first full weeks of the new year have been quiet, almost dull, in the character of their business.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Nov. 1908..	\$ 2,967,795	\$ 2,892,225	Exp. \$ 75,570
" 1907..	615,169	63,674,871	Imp. 62,959,702
Year 1908..	73,857,749	45,105,993	Exp. 28,750,846
" 1907..	54,211,240	38,949,557	Imp. 44,738,317
Silver:

" 1907..	4,187,378	3,604,406	" 584,973
Year 1908..	47,111,382	37,814,676	" 9,296,706
" 1907..	57,212,168	41,690,324	" 15,521,844

Exports of specie from New York, week ended Jan. 9: Gold, \$5500, to Chile; silver, \$908,400, to London and Paris. Imports: Gold, \$178,615; silver, \$89,457, from Cuba, Central and South America.

Gold—In London the price of gold on the open market has advanced, bar gold being quoted at 77s. 10½d. per oz., and American eagles 76s. 57½d. The Bank of France again took all the gold offered. Shipments of gold from New York this week were \$3,500,000, making a total of \$6,500,000 exported since Jan. 1, all to Paris.

Platinum—Dealers report business quiet, but that is usual at this season. Quotations are \$24.25 for refined platinum, \$26.25 for hard, and \$20@21 for good scrap.

Our St. Petersburg correspondent reports under date of Dec. 24: In Ekaterinburg, the small miners and forestallers offer crude platinum, 83 per cent. pure, at 5 rubles 10 kopeks per zolotnik (\$19.15 per oz.) The large dealers in St. Petersburg offer crude metal of the same grade at 19,000 to 20,000 rubles per poood, or about \$19.56 per oz. St. Petersburg dealers are holding back in expectation of higher prices.

Silver—The silver market has experienced a sharp advance during the past week on buying by Chinese banks and Indian bazars. Spot silver in London has been scarce, causing a premium of ¼d. for prompt over future deliveries. The market closes steady at 24¼d. in London.

SILVER AND STERLING EXCHANGE.

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—The reports from Europe have been rather discouraging and prices over there have given way from day to day. Foreign buyers have taken no interest whatsoever in the market, and domestic consumers could only be induced to place orders at concessions. A fair tonnage was sold at the decline. Lake shows less decline than electrolytic because there are fewer producers of that grade who have supplies that they are anxious to sell. The close is easy at 14½@14½c. for Lake copper; 14@14½c. for electrolytic in ingots, cakes and wirebars. The average of the week at which business in casting copper has been done is 13½@14 cents.

Copper sheets, cold-rolled, 20c; hot-rolled 19c, per lb., base. Copper wire, 15½c. base, carload lots at mill.

The London Standard market showed distinct weakness, prices crumbling away from day to day, and the close is easy at 62 2s. 6d. for spot, 63 for three months.

Refined and manufactured sorts we quote: English tough, 66; best selected, 66½@66; strong sheets, 67½@68.

Copper Producers' Association—At a meeting of copper producing, refining and selling interests in New York, Jan. 12, the report of the committee appointed at a previous meeting was received, and was adopted by the representatives present.

subject to ratification by the companies. A provisional organization was effected, with the following officers: President, T. L. Livermore, Calumet & Hecla; secretary and statistician, L. C. Graton, at present with the United States Geological Survey; executive committee, Messrs. McLean, Broughton and Clendenning. The report adopted formulates the plan, which is to secure and compile reports of production and stocks on hand by the refiners, and such statistics as to the production of crude copper as may subsequently be deemed advisable; such reports to be made monthly and given out promptly, and, of course, to give totals only. The executive committee contains representatives of the three classes of members, viz., producers, refiners and sellers. It is expected that the statistical work will begin in February next. The first report will comprise a statement of the production of refined copper in 1908 and the stock on hand Jan. 1, 1909, probably.

Tin—The operators in the London market, who all along had been supporters of the market, turned around and became heavy sellers. It is difficult to tell what brought about this realization, but it may, on the one hand, be due to the unfavorable statistical position of the metal, or, on the other hand, to the impending Banka sale. At any rate, the market experienced a severe decline, and showed on Jan. 12, when it reached the lowest point, a maximum drop of over £5. At these lower prices some support became manifest, especially also from consumers on this side, in consequence of which the market rallied and closes firmer at 126 17s. 6d. for spot, 128 10s. for three months.

Sales, in this market were made at as low as 27¾c. but the close is firm at 28½ cents.

Lead—Consumers having covered their requirements for this month, the market has again become quite lifeless. The close is weak at 4.15@4.20c. New York, and 4.05c. St. Louis.

The London market is also again neglected and closes somewhat lower at £13 2s. 6d. for Spanish lead, £13 5s. for English lead.

Spelter—The market for this metal has been rather quiet throughout the week. But little spelter is pressed for sale as, on the one hand, producers are well supplied with orders, and, on the other, they have no margin in smelting the metal at the present prices for ore. The close is 5.12½@5.17½c. New York, 4.97½@5.02½c. St. Louis.

The London market has been firm throughout the week and closes higher at £21 7s. 6d. for good ordinaries, £21 12s. 6d. for specials.

Base price of sheet zinc is 7c. f.o.b. La Salle-Peru, Ill., less 8 per cent.

Other Metals

Antimony—The market continues quiet, with no material change in prices. Quotations are 8½¢. per lb. for Cookson's, 8½¢. for Hallet's, and 7¾¢@8¢. for ordinary brands.

Aluminum—No change is reported, and the market is quiet. The Aluminum Company of America quotes 2½¢. per lb. base for No. 1 ingots; 33¢@34¢. base for sheets. Offers of foreign metal at 22¢. are still reported, but sales are said to be small.

Nickel—Large lots, contract business, 40¢@45¢. per lb. Retail, from 50¢. for 2000-lb. lots up to 55¢. for 500-lb. lots. These quotations are for spot nickel. The price for electrolytic is 5¢. higher.

Quicksilver—New York prices are steady at \$45@46 per flask of 75 lb., with a moderate trade. San Francisco quotations are \$45 for domestic trade and \$43 for export. The London price has been reduced to £8 7s. 6d. per flask.

Cadmium—In 100-lb. lots, 75¢. per lb., at Cleveland, Ohio.

Magnesium—This metal is offered in New York at \$1.25 per lb. in 100-lb. lots. The price is \$1.40 per lb. for 5-lb. lots.

Imports and Exports of Metals

Exports and imports of metals in the United States for the 11 months ended Nov. 30 are reported as follows, in the measures usual in the trade:

Metals.	Exports.	Imports.	Excess.
Copper, long tons	279,561	84,775	Exp. 194,786
Copper, 1907.....	197,452	106,681	Exp. 90,771
Tin, long tons.....	296	35,105	Imp. 32,899
Tin, 1907.....	530	35,487	Imp. 34,937
Lead, short tons.....	67,924	99,946	Imp. 31,922
Lead, 1907.....	47,481	72,137	Imp. 24,646
Spelter, sb. tons.....	2,471	842	Exp. 1,629

Aluminum, value \$369,738	Exp. 369,738		
Aluminum, 1907.....	Exp. 299,588		
Ores, etc.	Exports.	Imports.	Excess.
Zinc oxide, lb.....	22,056,313		Exp. 22,056,313
Zinc oxide, 07, 25,002,199			Exp. 25,002,199
Zinc dross, lb.....	15,966,311		Exp. 15,966,311
Zinc dross, 07, 17,548,258			Exp. 17,548,258
Zinc ores, lg. tons	23,311	44,734	Imp. 21,423
Zinc ores, 1907.....	16,011		
Antim'y ores, lb.....	3,668,502		Exp. 3,668,502
Ant. ores, 1907.....	2,668,902		Exp. 2,668,902

Copper, lead and nickel include the metal contents of ores, matte, bullion, etc. The exports given include reexports of foreign material. Zinc ores imported this year included 20,193 tons calamine and 24,541 tons other ore; in 1907 only partially reported.

Zinc and Lead Ore Markets

Platteville, Wis., Jan. 9—This week \$1 per ton was the highest price paid for zinc ore; the base price was \$40@41 per ton at 60 per cent. zinc. For 80 per cent. lead ore \$48@50 per ton paid.

SHIPMENTS, WEEK ENDED JAN. 9.

Year to Jan. 9.....	4,449,426		401,200

Highland, Lmden, Harker and Mineral Point are not reported. There was shipped to the Platteville Separating Company 167,100 lb. to the Joplin Separator Works, 70,000 lb. zinc ore.

Joplin, Mo., Jan. 9—The highest price reported paid was \$44.50 per ton, the assay base price ranging from \$40@43 per ton of 60 per cent. zinc. The latter price was bid today for next week's delivery. Silicate of zinc sold at \$19@22 per ton of 40 per cent. zinc and the highest reported was \$26. The average price, all grades, was \$38.80 per ton. The highest price reported paid for lead ore was \$52.50, the bulk of the ore selling at \$52, with medium grades selling down to \$50. The average price, all grades, was \$50.78 per ton.

SHIPMENTS, WEEK ENDED JAN. 9.

Notes.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold; lead ore prices are the average for all grades sold.

weather, came Tuesday, closing down a number of mines for several days. In the Joplin field the gas company cut off the natural gas from all mines using it under boilers, and a number about Webb City had an insufficient supply to operate continuously. The result is that nearly all mines using natural gas under boilers have taken out the gas fixtures and ordered coal. The demand for coal was so great that it could not be shipped in fast enough to meet the increased consumption, on so short a notice. A careful estimate indicates about 10 per cent. reduction in output.

For the first two weeks in 1909, as compared with last year, there was an increase in value of nearly 100 per cent. on a 60 per cent. increase in shipment. The lead shipment was increased only 8 per cent. on account of so many producers holding this mineral for a higher market.

Chemicals

New York, Jan. 13—The market is steady, and trading is quiet. But little contract business is reported, but trade is coming fairly up to expectations.

Copper Sulphate—Prices are unchanged, and no shading is reported. Quotations are \$4.75 per 100 lb. for carload lots, and up to \$5 per 100 lb. for smaller parcels.

Arsenic—The market is sluggish. Quotations are 3½¢. per lb. for white arsenic.

Nitrate of Soda—The position of nitrate in the United States Dec. 31 is reported as follows, in long tons, by Messrs. Mortimer & Wisner, New York:

	1907.	1908.	Changes
Stocks, Jan. 1.....	13,050	5,900	D. 7,150
Imports, 12 months.....	304,245	278,650	D. 25,595
Total Supplies.....	317,295	284,550	D. 32,745
Deliveries, 12 months.....	311,395	275,410	D. 35,985
Stocks, Dec. 31.....	5,900	9,140	I. 3,240
Afloat at U. S. ports.....	68,300	83,200	I. 14,900

The quantities afloat include all cargoes due to arrive at United States ports by April 15 next.

Current quotations here are 2.17½¢. for spot nitrate, and 2.15¢. for futures.

Imports and Exports—The imports and exports of chemicals and raw materials in the United States 11 months ended Nov. 30 were as follows:

	Imports.	Exports.	Excess.
Copper sulph. lb.....	7,360,870	F. 7,360,870	
Bleach, lb.....	66,622,581	I. 121,511	I. 66,501,470
Potash salts, lb.....	245,655,997	993,072	I. 244,662,925
Soda salts, lb.....	10,388,753	777,147	I. 9,611,606
Acetate lime, lb.....	62,666,154	F. 52,666,154	
Sit. of soda, tons	230,424	9,926	I. 220,498
Phosphates, tons	24,385	1,174,942	E. 1,150,557
Sulphur, tons.....	17,984	29,073	F. 5,189
Pyrites, tons.....	621,915		I. 621,915

Estimating sulphur contents of pyrites, the total sulphur imported was approximately 200,410 long tons.

Mining Stocks

New York, Jan. 13—The general stock markets this week were irregular, without any definite tendency, and weak rather

than strong. They were affected in different directions by various rumors, and to some extent by the steady outflow of gold to Europe. At the close a little stronger tone was manifest, chiefly because of a stronger feeling in the foreign exchanges.

The Curb market was also irregular and not particularly strong. The copper stocks were rather inclined to soften, on a moderate amount of selling. Other mining stocks were not in especial demand.

One sale of Homestake, of South Dakota, was reported, a small lot changing hands at \$90 per share.

Boston, Jan. 12—Beginning the week with a rather irregular market, copper stocks steadied themselves and closed better. Superior mining became a leader in the trading today, advancing from \$35.75 to \$38.50, on sales of 3000 shares. Winona rose to \$5.50, but Wyandott rose 50c., to \$3.50. Wolverine gained \$2.50, to \$152; Copper Range sold at \$78.50, with rally to \$79.50; Atlantic rose to \$18; Isle Royale to \$25; Lake to \$21.87½. Greene-Canea sold freely at \$11.50@12. North Butte held around \$82, and Amalgamated sold between \$81 and \$82. The end was firm.

On the Curb business was generally good, but with no special feature.

It is reported that a new development company is to be organized to work a group known as the Live Oak, in the Globe district of Arizona. The company will probably be floated here.

Spraying Coal Dust as a Colliery Safeguard

A Description of an Efficient Sprinkling System, with Detailed Costs of Installation and Operation as Carried on in the Mines of Utah

BY D. HARRINGTON*

"Man's inhumanity to man makes countless thousands mourn," said Robert Burns, referring to conditions existing a century ago; but the same statement applies very aptly to present-day industrial conditions in the United States and more especially to the coal-mining industry. The occurrence of disaster after disaster in late years in our coal mines, resulting in the loss of many hundreds of human lives, together with the publication of statistics proving that as compared with foreign countries, our coal-mining operations are far more destructive of human life than similar operations conducted by

the movement of maximum quantity at minimum cost, can operations be maintained at all. The presence of explosive gas without coal dust, would, of course, compel any wide-awake manager to adopt all available precautions to protect his men and property; the presence of explosive gas and quantities of explosive dust demands even more careful attention.

COAL DUST WILL EXPLODE WITHOUT GAS

While the opinions of coal experts throughout the world differ as to whether dust, without the presence of explosive gas, will explode, and scientists bring

and on one occasion, the explosion of 20 lb. of FFF black powder, with fine dust almost ankle deep on surrounding objects, failed to do more than local damage; however, on May 1, 1900, the accidental explosion of a 25-lb. can, or keg, of the same powder precipitated a holocaust in which over 200 human lives were lost. As stated above, not the slightest trace of explosive gas had been seen during the 20 odd years the mine had been worked previous to 1900 nor has any explosive gas been seen here to this day as far as can be learned. Here at least is one case in which gas, unless thoroughly

other nations, has awakened the humanitarian instinct of the American people; even the technical and trade journals are seriously occupying themselves in an attempt to discover causes of existing conditions. At its best, mining is a hazardous occupation and coal mining is probably the most dangerous branch, due to conditions peculiar to the product sought and to the fact that the margin of profit is so small and competition so keen, that only

forth many theories on this question, the people of Utah are absolutely sure that at least some kinds of coal dust do explode and do it without the presence or intervention of even the smallest trace of explosive gas. For over 20 years, the Winter Quarters mines in the east central part of Utah, were operated without encountering a trace of explosive gas, for the same length of time, the mine dust was regarded as absolutely non-explosive; windy, or blow-out shots without number had failed to create even a ripple on the usually calm surface of mining operations

"occluded," cannot be even remotely blamed. On another occasion, at the Sunnyside mine, some 45 miles distant from Winter Quarters, employees engaged at night on some repairs to the coal crusher used naked lights, and were severely burned by an explosion of coal dust, explosive gas being entirely absent. In the same plant, a 60-in. Steadman disintegrator was completely wrecked by an explosion, opinions differing as to whether the explosion was caused by the accidental intrusion of some giant powder from a car of coal

*Mining engineer, Salt Lake City, Utah.

coming out of the mine, or whether the finely divided dust within the disintegrator was responsible; later on, in the same plant, frictional sparks induced in the cages of a 60-in. Steadman disintegrator by the entrance into it of an ordinary short-handled shovel, dropped by a careless employee, caused a dust explosion, which burned the plant to the ground. The cause of this explosion was definitely determined to be due to finely divided dust, and here again, gas, as ordinarily understood, can hardly be said to be connected with the affair. The explosion at Winter Quarters, together with these later minor accidents, has convinced the coal-mining population of Utah that dry, finely divided coal in any quantity, either with or without the presence of explosive gas, is dangerous, and may be exploded; measures have been taken to render the mines of Utah safe as far as human ingenuity and human knowledge extend.

UTAH MINING LAWS

After the Winter Quarters explosion, the Utah legislature at the request of the State coal-mine inspector placed on the statute books the following: "Every owner, agent, manager, or lessee of mines within the State of Utah, shall provide and maintain a water system for the purpose of conducting water to the face of each and every working place and throughout the entire open part of the mine, in sufficient quantities for sprinkling purposes to wet down the dust that shall arise and accumulate in and around the mine, provided, that in mines and parts of mines where by reason of the natural wet condition, or the moisture derived from the introduction of steam into the air currents, or both, such sprinkling may not be necessary. And it shall be the duty of the superintendent, mine foreman and inspectors to see to it that this is done." This law still stands, hence all coal mines in Utah are compelled to install some system for watering down mine dust; in his reports to the governor of the State, the State coal-mine inspector places fully as much stress on the condition of the various mines as to dampness as he does to timbering, ventilation, or any other question affecting the safety or sanitary condition of the employees.

In order to make "assurance doubly sure," the Utah Fuel Company, realizing the dangers to both men and mine from indiscriminate shot firing, has devised and installed in two of its camps a system by which shots are exploded by electricity after all men are out of the mine. This system, which has been operated successfully for several years, almost completely eliminates any possibility of wholesale fatalities such as occur in collieries, and not even the long suffering shot-firer himself need dread the firing of the daily round of shots. As yet there is no law on the statute books of Utah bearing on

this subject, but in his report of 1905 and 1906 to the governor, the State coal-mine inspector made the following recommendation: "I would suggest to the Honorable Legislature of the State of Utah, which meets in January, 1907, that they make an amendment to the coal and hydrocarbon mining laws of the State of Utah, as follows: That it shall be unlawful for any miner, or any employee, in the coal and hydrocarbon mines of the State to use, or set off, any high explosive for the mining of coal, or taking down rock, during working hours, as all shots must be fired after the men are out of the mine, excepting those that will be needed to fire the same." While the last legislature failed to enact any law on this subject, it is entirely within the limits of probability that some such measure as above outlined will be placed, on the statute books the coming winter; it is to be hoped, however, that the clause "*excepting those that will be needed to fire the same*" will be omitted, and thus all human life safeguarded.

SPRAYING COAL DUST

The Utah coal is bituminous and hard, massive rather than laminated. It is not readily affected by weather agencies, and is of more or less coking character. The following is an approximate analysis: Fixed carbon, 46 to 57 per cent.; volatile matter, 36 to 44 per cent.; moisture at 115 deg. C., 1 to 4½ per cent.; ash, 2½ to 7½ per cent.; sulphur, 0.8 to 1.3 per cent.; calorific power, 5600 to 6000. The coal beds vary from 5 to 25 ft. in thickness, with generally sandstone roof and floor; the dip is from 1 to 6 deg., and the room-and-pillar system of mining is invariably used.

The mines are opened by means of slopes, or of level entries. If a slope is used the coal is let down out of the mine by electric hoists located underground, or pulled up from the mine by steam hoists from outside; if a level entry is used, the coal is handled by horses, or by electric locomotives, usually the latter. In two of the larger camps the coal is not cut or mined in any manner, all shots being fired "off the solid." In two of the camps, the coal is undermined by hand (Sullivan punchers having been tried and abandoned in one of these camps), while in another property, part of the mining is done by hand and part by puncher, the latter being used in the narrow work.

THE DUST PROBLEM

As human ingenuity has not yet devised a workable system of mining coal without the production of dust, all of these mines are afflicted with this troublesome substance and in considerable quantities; by common consent, since the Winter Quarters disaster, all dust is considered dangerous, and this fact, together with State

law requirements, has led the Utah Fuel Company to install sprinkling systems, each being a parallel duplicate of the others. The letter of the law could easily be carried out and its spirit evaded, as is so frequently done by coal operators, when they use water-carts, or wagons, or similar useless subterfuges, and by so doing, the item of "spraying," on the operating-cost sheet as well as on the construction or capital-charge statement, could be made practically negligible; however, remembering the lesson of Winter Quarters and numerous similar examples in Colorado, Wyoming and other States, the Utah operators installed a spraying system worthy of the name and deserving of reproduction wherever it is conceded that wetting coal dust is beneficial.

METHOD OF SPRAYING

To properly sprinkle a mine with accessible openings aggregating 50 to 75 acres and advancing at a rate of from 15 to 25 acres opened per year, requires about 20,000 gal. of water per day; such a mine with coal 5 to 8 ft. thick will employ 300 to 350 men and produce 1200 to 1500 tons per 8-hour day. The water should be under a pressure of about 50 to 100 lb effective head at nozzle, to allow of reducing the water stream to as fine a spray as possible and to give sufficient force to wash all fine dust completely from roof, walls or ribs, timbers, brattice, etc. Where it is possible to do so, this pressure should result from gravity by installing a tank or reservoir at a sufficient elevation above the mine. This tank or reservoir, should have a capacity equal to at least two or three days' sprinkling requirements to insure continuation of sprinkling even if the original source of water supply should, by accident, be temporarily shut down.

From the tank, or other storage receptacle, the feed pipe leading to the mine should not be less than 3-in. diameter and may be larger, depending on length, number of turns, number of streams to be used, grade, etc.; 3 in. is a minimum diameter in order to insure sufficient water with good pressure for at least 3 streams from a 1-inch hose, and in case of mine fire to insure two efficient streams from a 2-in. hose. This latter use of the water system is only incidental, but is clearly worth consideration when contemplating installation.

On the surface, the 3-in. feed pipe should be thoroughly protected from possible accident and from freezing; this is usually accomplished by burying it well under the frost line. The pipe should enter the mine through the return air course, avoiding reverse grades if possible, and should extend into the mine in such a manner as to allow distribution to the working faces with a minimum of laterals. Tees should be placed in this main feed line at selected points, so that

the haulage entries may be reached with auxiliary lines; these tees should have at least a 2-in. opening, and at intervals of 400 or 500 ft. along the main and auxiliary lines, other tees with a 2-in. opening reduced to 1 in., and having a $\frac{3}{4}$ -in. hose bibb, should be placed to be used in sprinkling the entry through which the pipe line runs, as well as any accessible neighboring place. The idea of placing the tee with a 2-in. opening and then reducing it to 1 in., or $\frac{3}{4}$ in., is to have all parts of the mine so equipped that in case of a mine fire, 2-in. fire-hose connections may be made with minimum delay.

The auxiliary lines into the main haulage entries should be at least 2 in. in diameter, and from this line, 1-in. pipe should be extended into all rooms. In case comparatively short side entries are turned off the main haulage entries, and rooms are driven from these side entries, $\frac{1}{2}$ -in. pipe is sometimes used in the latter entries, and either 1-in. or $\frac{3}{4}$ -in. pipe is placed in the rooms.

DETAILS OF THE SPRINKLING INSTALLATION

Gate valves are located at intervals along the main supply line, also on the auxiliary lines where they leave the main line and at intervals along these auxiliary lines in order that possible breaks may be repaired without interference with lines in other parts of the mine, and in order to be able to shut off the flow of water quickly in case of a break. These valves are either placed in boxes which can be locked, or the wheels, which act as levers, are removed and held by the waterman; the levers on the hose bibbs are also removed and kept by the waterman; this precaution prevents useless waste of water and possible damage to the mine by the irresponsible or malicious.

MEN ARE EMPLOYED TO DO NOTHING BUT SPRINKLE

The actual work of wetting down the dust is entrusted to one or two men as the case may be, two being required in a mine where 15 or 20 acres are developed per year; these two men have absolutely no other duties, not being called from their sprinkling in any but the gravest emergency. Part of their time will be occupied in making necessary repairs, or extensions, the remainder in sprinkling; or one man may continually sprinkle and one man work on the pipe lines, helping each other when the work at hand requires the services of two.

The waterman carries 150 to 200 ft. of $\frac{3}{4}$ -in. rubber hose which he attaches to the $\frac{3}{4}$ -in. hose bibbs before mentioned, opening the latter with the lever which he carries; he is instructed to thoroughly wet the roof, sides and floor of all accessible openings paying especial attention to the very fine dust near the working faces and along the haulageways. He is expected to keep all dust so damp that when loose

material is taken from the floor and subjected to pressure of the hand, the form thus fashioned will retain its shape on removal of pressure; all brattice must be kept damp, brattice on haulageways and manways being given particular attention.

By thus continually and systematically attacking the dust, the latter is at length saturated, a condition impossible to attain by spasmodic sprinkling, using a cart, pail or any other device by which the water must be transported on wheels. Moreover the playing of a finely divided spray under pressure not only settles that dangerous dust which keeps floating in the air, but penetrates dust bodies wherever located, while an attempt to wet them using pail or any other device not under pressure, would penetrate only a thin film of dust on the top, leaving the great body untouched and wasting at least 75 per cent. of the water used.

SPRAYING HAS NO HARMFUL EFFECT

The introduction of this considerable quantity of water into the mine workings has no visible harmful effect; the roof is not affected as it is by the introduction of steam into the intake air, and evaporation prevents any undue accumulation of seepage; the parts of the mine traversed by return air are kept moist by the condensation of moisture-laden air, thus insuring the elimination of dust deposits in those parts which are abandoned, but through which air currents must be sent. Objection to sprinkling has been made on account of the probability of causing spontaneous combustion, but not a single case has been reported, mine fires in Utah being almost unknown. This latter result is probably due to the fact that all parts of mines are kept damp, and the absence of heat thus prevents spontaneous combustion even where iron pyrites abounds; moreover, no fine coal is left in the mines except that which enters into the air temporarily, that which sifts from cars during handling and the small quantity which the miner fails to load out.

COST OF INSTALLATION

The cost of installation of a complete and effective sprinkling system will, of course, vary with the surrounding conditions, such as the extent of present mine workings, distance of water supply from the mine together with cost of bringing the water to the pit. We must also consider the possibility of getting elevation for a gravity head. As installed at Sunnyside, Utah, No. 2 mine, where partly pump pressure and partly gravity pressure were used, the cost was about \$7000, of which \$1500 was for labor and \$5500 for material. The labor charges included \$370 for carpenter work in building a 50,000 gal. redwood tank, and a 12-ft. timber trestle under same; \$230 was expended in excavating for, and in building the tank foundations; the total labor cost on the surface, there-

fore, was \$600. The expense incurred in placing the foundation for the 16x5 $\frac{1}{2}$ x10-in. Worthington duplex pump in the power house, also putting the pump on the foundation and connecting to the steam and water pipes was \$175. The cost of laying 3000 ft. of 3-in. pipe, 1000 ft. of 2-in. pipe, 20,000 ft. of 1 $\frac{1}{2}$ -in. pipe and 17,500 ft. of 1-in. and $\frac{3}{4}$ -in. pipe was \$725. Carpenters received \$4.50 per eight hours; masons, 50c. per hour; mechanics setting pump, laying pipe, etc., 37 $\frac{1}{2}$ c. per hour, and common labor, 25 and 27 $\frac{1}{2}$ c. per hour.

Material included the following, f.o.b. Sunnyside, Utah: Fifty thousand gal. redwood tank, 24 ft. diameter at bottom, 23 ft. diameter at top, and 16 ft. high, complete with bands, \$625; timber for trestle under tank, and lime, sand, etc., for walls was \$275; the 16x5 $\frac{1}{2}$ x10-in. Worthington duplex steam pump and fittings cost \$825; pipe, fittings, etc., as enumerated above, totaled \$3775.

The complete installation, therefore, cost about \$7000, and was suited for a mine producing annually about 300,000 tons; if this installation were charged directly to coal output and distributed over a year, the cost would amount to 2 $\frac{1}{2}$ c. per ton; if distributed over five years, the cost would be less than $\frac{1}{2}$ c. per ton. The installation at Castle Gate, where the annual production was also about 300,000 tons, cost slightly more than \$7000, while at Winter Quarters, where the annual output is 350,000 tons, and at Clear Creek with 350,000 tons, each installation cost considerably less than \$7000.

The annual cost of operation at Sunnyside including both No. 1 and No. 2 mines with 630,000 tons production is as follows:

ANNUAL COST OF OPERATION.

Wages 2 pipemen and 2 watermen at \$2.75 per day for 275 days.....	\$3025
40,000 gal. water per day for 275 days at 12c. per 1000 gal.....	1320
Labor, running pumps, supplying steam for same, etc.....	550
6 per cent interest on investment of \$14,000.....	840
Depreciation 10 per cent.....	1400
Extensions, repairs, hose, etc. (miscellaneous labor and material).....	1000
Total actual operating cost yearly.....	\$8135

As mine-cost sheets take no account of interest and depreciation, the total yearly operating cost to appear on cost sheet will be \$8135, which on a yearly tonnage of 630,000 will amount to less than 1c. per ton; where water is plentiful and the gravity system may be used, the cost per ton for operating will be less than $\frac{3}{4}$ c. per ton, certainly not an item to discourage any operator.

If this system was installed at the time of opening the mine, \$2500 would suffice in any ordinary locality, and extensions could be made to keep pace with development, and be charged out to coal production without creating any particular notice. These extensions in a newly opened mine producing about 500 tons per day, or 11,500 tons per month in a seam 10 ft. thick where development is being rushed, will

amount to about 60 ft. of 3-in. pipe monthly, costing \$15, 300 ft. of 2-in. pipe in main haulageways costing about \$30 each month, and 700 ft. of 1-in. pipe with a monthly cost of \$40; this makes a total of \$95, or about 4/5c. per ton. This cost would probably increase slightly until such time as retreating work is begun, and then the time will soon come when the pipe recovered will amount to as much, or to more than the pipe extended; when this occurs, the total cost of spraying will be reduced to less than 1c. per ton, as shown above at Sunnyside.

Miners who have been employed in Utah mines and later go into neighboring States to work, are horrified at what they freely term the criminal neglect and carelessness of coal operators, and many of these miners refuse to work in the dry and dusty mines. Mine owners in Utah place such stress on effective spraying, that they have been known to close down a mine producing over 1000 tons daily until frozen water pipes have been thawed to permit resumption of sprinkling. The mine manager naturally hesitates to add 1c. per ton to his cost record, and directors and stockholders are not fond of parting with 1c. per ton on a large production, where the aggregate cost often totals several thousand dollars annually; however, when these operators and mine owners recall the bitter experience of Winter Quarters and other mines where the money loss to the company amounted to several hundred thousand dollars, without considering the human suffering entailed and the prestige lost, the added safety obtained by thorough spraying together with anxiety spared all connected with the company, generally causes the coal magnate not only to be reconciled to the addition of 1c. per ton to his cost sheets, but even to be thankful that by having done so, he has probably escaped paying a far heavier tribute to the gods of destruction. This article will be followed by a description of the modern system of firing all shots electrically in the Utah mines.

Safety Lamps in the Coal Mines of Foreign Countries

The Commission on Illumination, appointed by the Société de l'Industrie Minérale, begins its report, in the *Bulletin* of March, 1908, with a review of the laws of the several coal-mining countries of Europe relating to the use of safety lamps.

In France a safety lamp of standard and approved type is obligatory in all coal mines, except that a naked flame may be carried into a downcast air shaft. The safety lamps are supplied by the operator, and each one has a number, a record of which is required to be kept by the proper official on the surface. Each workman

receives his lamp cleaned, burning and in perfect condition; if it is found subsequently open or out of order, he is held responsible and is disciplined.

In Austria naked lamps are forbidden except in downcast air shafts. The type of safety lamp required to be used burns benzine, has two gauzes, a magnetic lock and a magnetic relighter. Portable electric lamps are also permitted. All lamps are officially inspected once a year.

THE COST OF ELECTRIC LAMPS HAS HINDERED THEIR ADOPTION

In Germany the rules are similar except that portable electric lamps are permitted only under the same conditions as are naked lamps. The price of electric lamps and the cost of maintaining them have thus far hindered their wide adoption. Safety lamps have one or two gauzes, according to the places in which they are to be used. They do not have the mantle.

In Belgium naked lamps are forbidden in all coal mines whether gassy or not. In moderately gassy mines safety lamps of well known types and portable electric lamps are permitted. The former are required to have the mantle, but its condition of fixedness is optional with mine managers. Only phosphorus relighters, ignited by friction, are permitted. Relighting stations are located near downcast air shafts.

In Spain safety lamps are compulsory in gassy mines and incandescent electric lamps are permitted under certain conditions of isolation and protection. Arc lights are not allowed.

In England safety lamps are not demanded except in such parts of a mine as shall have "a dangerous proportion of inflammable gas," which loose terms leave a good deal to personal discretion. In Wales, however, naked lamps are very rare. The mantle, without being compulsory on a safety lamp, is widely used, even on lamps with but a single gauze, and workmen are generally forbidden to lift the mantle. Electric lighting is permitted under certain safeguards.

Accidents in Coal Mines

According to estimates made by the Geological Survey, there has been a falling off in the number of deaths in coal mines for the year 1908, and the number of deaths will be several hundred less than in 1907. In that year more than 3125 men were killed in the coal mines of the country—a death rate of 4.85 for every 1000 men employed—from three to four times as many men per 1000 as are killed in any coal-producing country of Europe. In December, 1907, four explosions caused the death of 700 men. During 1908 there were but two accidents in which the loss of life was heavy; one in January at the

Hanna mine, in Wyoming, with a loss of 70 men; the other, Nov. 28, at the Marianna mine, in Pennsylvania, which resulted in 154 deaths.

ALL EXPLOSIVES TO BE STANDARDIZED

The experiment station at Pittsburg announces that much of the danger heretofore experienced is due to the so-called "safety" explosives. It is the purpose of the Government to continue these experiments until the explosives of the country are standardized in such a manner that the miner will have a definite idea what these explosives will do. After the Government has gone far enough in its experiments, a bulletin will be issued recommending as permissible explosives, such as stand the test.

The Survey is also laying stress upon experiments said to show that coal dust is an explosive as dangerous as firedamp. The officers at the Pittsburg station are seeking to find some method by which this dust can be prevented from being a serious menace. These investigations are expected to accomplish a reduction in the number of men killed in the mines, and a saving of the waste in mining coal. The use of improper explosives, as well as the improper use of suitable explosives, is said to result annually in the waste of great amounts of coal. The use of too high charges in blasting, or the use of unnecessarily violent explosives, shatters much good coal, converting fuel into dust which may itself be explosive and become productive of further damage. Such explosions often loosen the roof of a coal mine, causing falls of top rock, and resulting in increased fatalities.

West Africa, the Gold Coast Colony and Ashanti in 1908

By W. FISCHER WILKINSON*

The gold production during 1908 will amount to a value of about £1,183,000, which is somewhat in excess of that obtained in 1907. No new mines are crushing and the increase is mostly due to the Taquah mine, which milled the whole year, while in 1907 its production was limited to the closing months.

The accompanying table gives a list of the principal mines showing the approximate results obtained, the returns for December being necessarily estimated.

TACUAH AND ABOSSO MINES

The Taquah mine, which heads the list, commenced regular crushing in September, 1907. This mine is working banket ore. The mill of 50 stamps is run by a gas engine and producer plant, the first on the coast; the plant is reported by the gen-

*Mining engineer, London, England.

eral manager to be an unqualified success. For the period September, 1907, to June, 1908, the 50-stamp mill crushed 46,234 tons (2000 lb.) for a return of gold of the value of £162,243 or 68.36s. per ton. During this period the mill ran only 59.55 per cent. of its possible full time owing to want of ore and breakdowns of the old machinery in use. The costs, including development redemption (6.5s.) and London expenditure (2.4s.) but not depreciation, were 42.1s. per ton milled. With better running time the costs will no doubt be less but the grade seems high compared with the other mines along the banket section. The ore reserves are given as 233,941 tons, value not stated, but they include 176,971 tons assaying 21.6 dwt. The greater portion of the profit made has been spent on capital expenditure, and no dividend for the financial year is paid, but the directors announce an interim dividend of 10 per cent. for 1908 payable in January, 1909.

extraction and timbering 7s. 1d., treatment 10s. 11d., general charges 7s. 1d., but excluding development, London expenditure, depreciation and sundries which total up to another 16s. per ton, making a total cost of 41s. per ton compared with 40s. during the previous year.

The event of the year was the discovery by J. N. Justice and since called "Justice's Find," of a large orebody composed of a soft oxidized and decomposed schistose rock turning in depth (below the zone of oxidation) into a fairly hard basic rock still showing schistose structure, highly impregnated with pyritic mineral chiefly arsenical, and carrying fluctuating, but payable, quantities of gold. No. 1 level, which is about 35 ft. from the surface, over a length of about 400 ft. crosscuts across the deposit have given the following results: 61 ft., 21.2 dwt.; 80 ft., 12.7 dwt.; 83 ft., 11.5 dwt.; 68 ft., 11 dwt.; 63 ft., 7.6 dwt.; 77 ft., 35 dwt. and 66 ft., 17.4 dwt.

that cannot leave much profit, if any, judging by the costs of the other mines. The Broomassie mine with 20 stamps treats very high-grade ore. For the year 1907 bullion to the value of £73,085 was recovered, an amount which was balanced by cost of working, development redemption, depreciation and London expenses. The working costs for the first three months of 1908 but excluding development and depreciation, were in round figures 30s. per ton. The returns for 1908 show a considerable increase.

OUTLOOK

Looking at the results obtained at the different mines, it will be seen that the results of the year were not very profitable, yet there is a promise of better results in the future. The industry continues to gain by experience, and costs are certainly coming down. Gold undoubtedly exists in large quantities and over a wide area and if only the cost of working can be reduced to 20s. a ton instead of 40s. a ton as it now appears to average, when development redemption, depreciation, etc., are allowed for, a prosperous future awaits the industry.

In spite of the disappointing results that the country has given to those who have put their money into mines, there are not wanting those who have faith in a large reduction in working costs being possible. It was announced late in the year, an announcement that caused great activity in the "Jungle" market, that the Consolidated Goldfields of South Africa, which is already interested in the New Gold Coast agency and the Cinnamon Bippo mine, which was reopened last August, was providing working capital for three mining companies in the Wassau district, the Efuenta, the Fanti mines and the Wassau West Amalgamated.

An event of the year that needs notice is the discovery of petroleum in southern Nigeria. A company was formed to work it. A discovery of oil is also reported on the Gold Coast about 30 miles from Axim.

GOLD PRODUCTION OF GOLD COAST COLONY AND ASHANTI, SINCE 1880.

Water should not be allowed to drop down an upcast shaft, as it retards ventilation. In down-cast shafts the dropping water cools the air, but may increase the moisture in the air even to the saturation point. If the stopes are warm the cooling of the air is less beneficial than the saturation is detrimental.

			£1,183,066	

* Ball mills equivalent.

The Abosso mine, which is managed by the same men as the Taqaah, has a 50-stamp mill, 20 having been added in February, 1908. During the financial year ending June 30, 1908, 44,021 tons were crushed, the recovery value being 50.4s. and the costs, including development (5.25s.) and London expenditure (1s.) but exclusive of depreciation, 35.2s. per ton milled. The costs were above the normal owing to a series of accidents at the mine, the lower levels being more than once flooded. The ore reserves at June 30, 1908, were estimated at 210,801 tons of 18.7 dwt. value. The dividend is the same as last year, namely 10 per cent.

ASHANTI GOLDFIELDS CORPORATION

The Ashanti Goldfields Corporation showed a net profit for the year ending June 30, 1908, of £34,646, most of which was spent on capital expenditure, so that no dividend was declared. The company operates a group of quartz mines round Obuassi and treats the ores partly by wet stamp milling and cyaniding, and partly by dry crushing, roasting and cyaniding. For the 12 months ending June 30, 1908, there were crushed wet 43,135 tons, and dry 16,021 tons, total 59,156 tons of a total value of £171,033 equal to 56s. per ton. The costs are given as 25s. 1d., made up of ore

How far the value is maintained in depth is not yet known, but the indications in No. 2 level, 100 ft. vertical below No. 1, are promising. Enough work has, however, been done to allow of estimates being made of a large tonnage of 14-dwt. ore being available which can be cheaply won by open workings. The ore is refractory and the great bulk of the gold cannot be detected by simple panning, which may be the reason why the deposit was not worked by the natives. Although refractory a good extraction is obtainable, without roasting, by sliming and filter pressing. In consequence of this fortunate and unexpected discovery an extension of the plant is now being considered.

OTHER PRODUCERS

The Prestea Block "A" mine made a large gold production, but a yield of about 34s. does not allow of much margin of profit as costs are at present. In the November report it is officially stated that notwithstanding present conditions the mine is paying its way, so probably the costs are about the yield figure. Improved results are expected when the railway connection with Tarkwa is completed, the completion being expected next autumn.

The Abontiakoon Block 1, the Bibiani and the Wassau have also grades of ore

Alluvial Working at Addison's Flat, New Zealand

By A. GORDON MACDONALD*

At Addison's Flat, about eight miles south of Westport, there are several alluvial claims worked by a system of hydraulic sluicing, the tailings being elevated by means of a "back balance."

The gold occurs in several leads at or near the bottom of the alluvial wash, which is about 50 ft. thick. The leads run in an approximately north-and-south direction. The bedrock is a blue, marly clay of Lower Miocene age,¹ known locally as "marine bottom," or "blue reef." On this rest layers of black sand and fine gravel, of marine deposition, varying in

nels, one on each side of the old, original drives, and more or less parallel to them, were driven to work each lead. In time these were also worked out and abandoned. Some timbers used in these workings can be seen in the present working face.

At the present time water has been brought to the claims, and the whole of the ground, excepting a few "duffer bars" between the leads, is being sluiced away. The water is brought to the edge of the workings by a flume, and is then led by pipes to the face, thus giving a head of about 50 ft. This pressure is sufficient for hydraulicking the gravel, but obviously insufficient to elevate the tailings by means of a "blow-up" or hydraulic elevator. Hence the back balance is used to hoist the coarse tailings out of the pit.

truck, having a capacity of from 18 to 20 cu.ft., is hauled by a water tank, the two being connected by a steel-wire rope, which makes several turns around the brake drum at the head of the incline. The angle of inclination of the tramway is about 30 deg. from the horizontal, and the axis of the brake drum is perpendicular to the plane of the tramway. The length of the incline is about 120 feet.

The truck comes down underneath the hopper, and is filled with tailings by opening the bottom doors. At the same time the tank is being filled with water at the top of the incline by means of a 12-in. pipe fed from a cistern. When full the tank, weighing more than the loaded truck, hauls up the truck filled with tailings. On reaching the top the truck is disconnected and run out to the dump.

THE "BACK BALANCE" IN OPERATION

THE BOTTOM OF THE INCLINE, SHOWING TANK AND HOPPER

thickness up to 20 ft. It is this part of the alluvium that contains the leads of gold. Overlying this fine wash is a deposit, from 20 to 30 ft. thick, of coarse granite boulders. This portion of the wash contains little gold.

In the early days of the district these leads were worked by sinking shafts to them and then removing the richest portions by driving, the gravel being hoisted through the shaft; as soon as the leads began to get poor, they were abandoned. Some time later they were again worked, this time by driving tunnels to drain the workings. Generally two of these tun-

As many as possible of the large boulders are thrown to one side, the rest being sluiced down a launder about 200 ft. long, placed in a cut in the bed rock and lined with wooden blocks. From this sluice the gravel passes over a flat, punched screen about 12 ft. long by 3 ft. wide. The coarse material passing over the screen is delivered into a fixed iron hopper, called locally a cage, which is in the form of an inverted truncated pyramid, with a double iron door at the bottom, controlled by a lever. From this hopper these coarse tailings are loaded into a car and elevated by the back balance.

THE BACK-BALANCE HOIST

The back balance is worked on an inclined double tramway, up which the

Another truck is immediately hooked onto the rope, and filled with water from another 12-in. pipe. When the tank reaches the bottom an arm, connected with a door in the bottom of the tank, strikes a horizontal wooden bar, thus opening the door and emptying the tank. The truck filled with water then descends, hauling up the empty tank. Another cageful of tailings is now discharged into the truck and is hauled up as soon as the tank at the top is filled with water. By this means about 30 truckloads of tailings can be disposed of in an hour.

The water used for filling the truck and tank is not wasted, but is run, together with the fine material passing through the hopper, over the gold-saving tables, which are about 800 ft. distant from the hopper,

*Acting director, Westport School of Mines, Westport, New Zealand.

¹Alexander McKay, report on the geology of the southwestern part of Nelson and the northern part of Westland, p. 56.

the two points being connected by a tunnel. The tables are arranged in five steps. Each step is 48 ft. wide by 3 ft. long in the direction of flow, with a baffle board and well, 8 in. wide, between each step. The total fall is 21 in., or a little more than 1 in. to the foot. The tables are covered with blanketing to give a better surface for catching the gold. To get rid of the tailings from the tables a tunnel over 2000 ft. long has been driven through

Smelting Progress in California

SPECIAL CORRESPONDENCE

A conference has been held between the board of supervisors of Contra Costa county, Cal., representatives of the Selby Smelting Company, the Peyton Chemical Company and the Mountain Copper Company, and certain citizens of districts

of the farmers declared that it was not the intention to force any hardship upon the smelting interests. The smelting men declared themselves ready to meet the requirements of the new ordinance. They wanted 90 days time but this was reduced to the 60 days.

What was formerly the Oakdale Ore Purchasing Company and is now the Richmond Reduction Works, has purchased the buildings of a foundry at Point Richmond, on San Francisco bay, where there is connection with both rail and tidewater. The buildings have been remodeled to suit the requirements for handling ores, concentrates, etc. The company is purchasing sulphurets, chlorination tailings, etc., in the Mother Lode counties of California and elsewhere, and treating them at Point Richmond.

Aluminum and Electrical Work

According to J. T. W. Echevarri in a paper recently read before the Institute of Metals, the price of aluminum now ranges from £65 to £100 per ton, which gives a wide and increasing field of usefulness. The saving that can be effected by substituting aluminum for copper for overhead conductors is so large that in countries where long overhead transmission lines are common the lighter metal is preferred. At its present low price,

TOP OF INCLINE, SHOWING BRAKE DRUM AND TANK-CAR FILLING

the "blue reef." This tunnel discharges the tailings into a creek.

Eight men work the claim; three in the face sluicing the ground, two at the hopper, and three at the head of the incline running the back balance and dumping the cars. In the evening all the men go to the tables, take up the blankets and wash them in two tubs, placed on rails to facilitate the work. The concentrates thus obtained are treated in the amalgamation barrel. Quicksilver and caustic soda are added and the charge is mixed, the barrel being run by a small water wheel, until the blankets are again washed, which is usually every 24 hours.

Notwithstanding the fact that the best of the leads has been worked out, that the tables do not make a high saving of gold, that amalgamation does not give a high percentage of extraction from the concentrates, and that only three of the men are engaged in sluicing down the dirt, the remainder performing what might be called dead work, the claim is giving good results, paying, on an average, £4 a week per man.

Rhodesia is expecting a boom in copper, consequent upon the success of the Edmondian copper mine.

The output of gold from the Gold Coast Colony, including Ashanti, for October, 1908 was 24,552 ounces.

GENERAL VIEW OF THE WORKINGS, ADDISON FLAT, NEW ZEALAND

which had complained of smelter fumes from the smelting plants of these companies. As a result the smelting companies have been granted 60 days time in which to install appliances to prevent the distribution of damaging gases. This is in compliance with a recent ordinance passed in the county in the interests of certain farming districts, where it was claimed that vegetation was being injured. At the conference referred to the representative

the author believes there is an extensive field for the metal for insulated underground cables. For busbars and back connections in switchboards it is already being increasingly used.

In 1907 four tons of silver ore, containing 2959 oz. silver were produced from the Perran mine in Cornwall. This was the only producing silver mine in the United Kingdom.

Developments in Gold Dredging During 1908

The Year Was a Prosperous One in the Industry and Witnessed Great Activity in California and Important Progress in the Klondike

BY JOHN POWER HUTCHINS*

The year 1908, one of strained financial conditions, had no bad effect upon the operation of gold dredges. On the contrary, there seemed to be unusual prosperity in comparison with mining other metals than gold, for mining for other metals was very seriously affected by the fall in prices. Gold dredging, in having an unlimited demand and a constant price for its product, is surely an attractive kind of mining.

The hard times interfered with progress in searching for and equipping new dredging enterprises, although there was a healthy search for new ground and this search was rewarded in several instances by finds of good ground.

Ground that can be worked successfully with floating dredges is hard to find. The most common drawback is a lack of sufficient gold. It is remarkable that there are so many areas containing only a few cents per cubic yard immediately adjoining ground which furnished rich diggings. Many instances can be cited of creek valleys having all the essential characteristics of dredging deposits except sufficient gold surrounded by old bench diggings with records of wonderful yields. There are also numerous creek gravels with sufficient gold, as compared with California dredging fields, but lacking the features that would make it possible to exploit them with floating dredges. There is usually too low a content of gold or if there is more than a few cents per cubic yard there are big boulders, or hard, rough bedrock, or too much clay, or hostile environment or some other factor to raise dredging costs to a prohibitive level.

There is at present an intensive search for new dredging fields and with good results. Countries possessing cold climates and frozen ground are attracting greater attention. It is probable that the search now being conducted in Siberia will result in developing important dredging fields. A similar activity is noted in tropic South America. Colombia is under investigation, and it is probable that several dredges will soon be installed there. There have been many dredging failures in South America, but only recently has a first-class modern dredge of California type been installed in that continent. This dredge was built on the Atrato river and is now being moved to the ground where it will be operated.

CALIFORNIA

Dredging was generally prosperous in the United States. California showed a healthful condition. Some very powerful dredges of large capacity were built and these are doing profitable work in ground that only a few years ago was thought to be undredgable. Dredging at Oroville had no unusual incidents. A number of the older dredges were scrapped. The Anti-Débris Association was active and enjoined dredging operations where no real damage was done. The city of Oroville enjoined one dredge company which carried on work in the river in a way supposed to cause choking of the river bed so as to give trouble during freshets. There was more or less agitation in cities situated on other rivers in which dredging is carried on. As a notable instance, Sacramento took steps to investigate alleged damage done by the dredges near Folsom. None of these dredges work in the river, and the only possible damage that can be done is by the inconsiderable amount of material held in suspension in the water that runs from the dredge ponds. This probably amounts to not many hundredths of an ounce per gallon of water and it is of such character that it will not settle where there are no river or tidal currents.

The first large dredge to be installed in northern California began operations. This is the first large dredge to begin work in California in gravel differing from that at Oroville and at other places on the flanks of the Sacramento and San Joaquin rivers. The dredging province of California was extended somewhat by the investigation of rivers tributary to the San Joaquin and formerly considered undredgable.

MONTANA

Some interesting dredging was done in Montana, furnishing an opportunity for a comparative test of a remodeled dredge fitted with gold-saving tables. This dredge formerly had a sluice box. It is reported that dredging the tailings from the dredge in its original form with the remodeled machine yielded a recovery of 5 per cent. of the original saving. This is about the same as that found in drilling the tailings to ascertain their gold content and is noteworthy. The sluice box was supposed to be less efficient as a gold saver than the tables, resulting in a considerable loss. These figures show that the loss was inconsiderable, and it is

not improbable that, had the tailings been worked a second time by a sluice-box dredge, an equal saving might have been effected.

There is, unfortunately, still uncertainty as to the relative merits of sluice box and table, the relative merits of which are not easy to determine. Any procedure to gain knowledge is expensive, and it is extremely difficult to make accurate determinations when handling large volumes of material as in dredging. The gold dredge with the largest buckets in the world, 15 cu.ft. capacity, is owned by the same company. This dredge has a sluice box, and by reason of recent experience with the remodeled type and of other, though minor, considerations, it will not be immediately changed to the table type.

A gold dredge is being installed near Butte. It will operate in material that is by some mining men not considered to be placer material in the limited sense of the word. The ground has some peculiar characteristics, and the operations of the dredge will be watched with considerable interest. Montana has large areas of ground which may, on investigation, prove to be dredgeable.

IDAHO AND COLORADO

Dredging was carried on in Idaho with success. In one instance ground worked several times, by hand is now being dredged. In this area the richest returns are often obtained in the ground which has seemingly been most thoroughly worked by hand methods. In one place, an improved dredge is being installed on ground that has been idle for three years after being dredged for five years.

A similar change is reported in Colorado where dredges failed in the early days, and at present modern powerful dredges of large capacity are working successfully. Two dredges originally located in Clear Creek were moved, one to a place near Breckenridge, Colo., and the other in Calaveras county, California.

THE KLONDIKE

Dredging in Klondike made important progress during 1908. Steam thawing was practiced on a large scale and at a lower cost, and less difficulty was experienced. Ground with a high gold content was found, and stripping accompanied with drainage so as to lower the water level produced progressive thawing. It

*Mining engineer, 52 Broadway, New York.

is expected that this stripping and draining will, after a time, make it unnecessary to use steam thawing except in rare cases. Thawing will (it is thought) progress deeper each summer until it reaches bedrock and the ground will then remain unfrozen. There is, however, nothing certain about this, for the ground may freeze again during the winter. The average temperature for the year is considerably below freezing. Gravel stripped, drained and thawed to a depth of more than 15 ft. has been known to freeze solidly during the next cold season. There is much ground that now has all the characteristics of stripped and drained creek beds, yet this ground thaws superficially in summer and freezes again in winter. It is to be hoped that stripping and draining will result in progressive thawing to bedrock in the Klondike creek beds, for if successful the practice could be applied elsewhere, thus extending the dredging province considerably.

Stripping by thawing alone did not prove successful in Klondike, for it was found that material did not thaw to any considerable depth below water level. During 1908 the gravel was drained and much better results were accomplished. As predicted in this JOURNAL (Jan. 4, 1908, p. 58 and Mar. 7, 1908, p. 512) it was found that gravel does not thaw below water level when it is of the depth generally encountered in the Klondike creeks. When there is a considerable depth of overburden, which may be stripped by hydrauliclicking, and a relatively shallow section of gravel is left for dredging, this stripping, aided by draining will usually result in seasonal thawing to bedrock.

Dredging in its limited meaning is applied only to unfrozen areas. Where frozen ground is encountered other methods incorporating some of the features of drift, hydraulic, or other open-cut mining practice is applied. There was considerable progress in dredging in the Klondike, and the high gold content of some of the gravels will result in exploitation even though the working cost may be high.

Dredging in unfrozen ground has been carried on with great success. The fact that where most of the dredging was prosecuted the ground was only partially frozen, was a great advantage.

Recent installations of dredges include buckets of 7 cu.ft. capacity. Several dredges with 5-cu.ft. buckets were installed two years ago. A 7-cu.ft. dredge installed in 1905 was successful from the beginning. The larger bucket seems to have shown its advantages in Klondike as elsewhere. This experience is similar to that of dredge men in California where there was for a time a retrogression toward small buckets for working ground suitable for large dredges.

ELECTRIC ELEVATORS

The electric elevators used in Klondike in 1908 may be classed with dredges. The machines were installed in the creek beds where it was thought that dredging could not be prosecuted advantageously. The elevators consist of a chain of buckets mounted on a ladder, the buckets being heavier than the stacker buckets of a dredge because they must stand the strain of excavating material from a sump. The material is conducted to the sump by driving with a stream from a hydraulic nozzle. Two centrifugal pumps are used to raise the excess of water that the buckets do not lift.

The method which is one form of open-cut mining employing sluices for saving the gold, allows the sun and air to do most of the thawing; it also exposes the bedrock and allows it to be thoroughly cleaned by hand. The elevators are not mobile, and since they must be moved occasionally they involve a loss of time.

A machine of this type used in Australia has some advantages in the matter of mobility. Material is hydrauliclicked into cuts that conduct it to a sump; it is not driven to the sump as in Klondike. It is raised by a centrifugal pump to the sluice, the pump being placed on a barge. When it is advantageous to move, the pit is flooded, the barge floated to a new position, the water pumped out, the barge settling on bedrock and the work is resumed. This arrangement gives fair mobility.

There are no data for comparison of the two methods. For the Australian plant, a working cost of 4.6 to 5.6c. per cu.yd. is given when gravity water is available and 6 to 9c. per cu.yd. when water must be pumped by steam power to the hydraulic nozzle.

It is interesting to note that the operation of the elevators in the Klondike is similar in all essential features to one carried on in 1903 on El Dorado creek, also in the Klondike. Material was hydrauliclicked with but small pressure to a bucket elevator operated by steam. A centrifugal pump run by steam handled the excess of water. This plant operated on a small scale with but little water under low head and the fuel cost was heavy. Its operation was discontinued and other methods were applied.

The new operations with elevators will have plenty of water under high head, which will permit working a large pit thus exposing large areas to the thawing action of sun and air. The use of electric power on the elevator and pump will also effect a great saving as compared with steam power. This enterprise is a good instance of what may be accomplished by a powerful corporation working on a large scale.

The open-cut method most commonly used by the one-man proposition of re-

cent years in the Klondike and the so-called elevator method recently installed possess several similar features. By the old methods stripping was effected by ground sluicing, by means of horse or steam scrapers or in some other way. The bedrock gravel was shoveled into cars or skips or other receptacles and elevated to the sluices. As now worked the stripping and transportation of gravel to the elevator is effected by hydrauliclicking and the elevator lifts it to the sluice. Had a supply of water been available elevators would have been used very generally in the early days.

SEWARD PENINSULA

On Seward peninsula, in Alaska, dredging was successful wherever proper methods have been employed. Where failures have occurred, management such as would have resulted in failure elsewhere was responsible. There are, to be sure, a number of difficult problems connected with the hostile conditions of the far north. Frozen ground is a drawback more than a "bugaboo." There are areas of unfrozen ground in Alaska and some of these will be dredged at good profit. Whether the large volumes of tundra gravel will ever be exploited successfully by the dredging method is problematic, but it is likely that if frozen ground can be thawed out successfully in Klondike by stripping and draining the tundra gravel may be treated similarly. However, the problem of preventing gravel thawed in summer from freezing solidly during the following winter is yet to be solved.

OTHER COUNTRIES

Investigations are being carried on in Siberia and new dredging ground is being developed. Where there has been such a large output of gold, most of it by placer methods, it is likely that there will be a considerable development of dredging ground.

Dredging in West Africa experienced the difficulties encountered elsewhere in the tropics. The bad sanitary conditions had a considerable effect upon costs. In one instance much time was lost by reason of continued high water. Buried timber was also an obstacle.

In Australia, dredging was carried on as formerly. The water-power dredge, which is operated by impact water wheels the water being conducted upon the dredge through an articulated pipe, worked satisfactorily. Dredges have failed on areas in Australia because of their inability to excavate difficult material or bedrock. It is probable that if large, powerful dredges of the California type were installed on some of these areas success would be attained. Some of the California dredges are now operating in ground so hard that it cannot possibly be

dredged at a profit by small, weak dredges, such as are generally used in Australia. It is well to compare the cost of a large California dredge, about \$150,000, with that of the type used in Australasia, about \$35,000.

In the Philippines the industry had its vicissitudes, but it is hoped that changes and improvements in the dredges will result in better working. Difficulties due to tropical environment are experienced in the Philippines as elsewhere in the torrid zone.

Another dredge was installed in Dutch Guiana and it is said that although it operated in rich material, mechanical difficulties have caused much trouble. This dredge was manufactured in Europe and is lighter and much less powerful than the California type.

Two dredges were installed in Brazil, where it is expected that both gold and diamonds will be extracted. Neither of these dredges has as far as I know worked profitably as yet.

In Tierra del Fuego, dredging seems to have been successful in but few operations. In several cases, machines of poor design and material were installed. No dredges of the California type have yet been built in Tierra del Fuego. In one instance, peat excavated from the overburden ahead of the dredge is said to have been used as fuel. English coal at more than \$15 per ton has been generally used. The dredging season is about 10 months in duration.

DESIGN AND CONSTRUCTION

There were no radical changes in dredge design and construction during 1908. There were improvements in the nature of refinements in details of design and manipulation. The close-connected bucket was again found to work more satisfactorily than the open-connected type. In several cases in which 3-cu.ft. close-connected buckets were substituted for 5-cu.ft. open-connected buckets, considerable gains in capacity and saving in power were noted. This was particularly noticeable where indurated material was dredged on a headline anchorage. Considerably less wear, tear and breakage was also noted, for there was much less surging with the close-connected bucket. Heavier construction is more common and the limit does not seem to have been reached in this respect.

No gold dredges with steel hulls have yet been built in the United States. Wooden hulls have not been satisfactory, the life of the wooden hull in California being only about 10 years. Wooden hulls also become much distorted in a few years. To prevent distortion more structural steel has been used and longitudinal and lateral trusses are now incorporated. Time alone can determine whether these

trusses will prove effective. Steel hulls would probably be more rigid and more durable than those of wood, and would also be more costly. There seems to be no immediate prospect of a dredge with a steel hull being built in the United States.

Steel hulls should be more generally used in tropical climates where wood-boring insects and decay make the life of a wooden hull a short one. Easier transportation of the steel plates than lumber is also an important consideration where inaccessible regions are concerned.

The respective advantages of quicksilver riffles and cocoa matting were better determined during the year than ever before. It is now generally accepted that under normal conditions, where there is a clean dredge pond and clean gold, little difference in the respective percentages of saving will be noted. When the dredge pond is dirty, as generally occurs with dredging not conducted in a river, the quicksilver riffle is superior. Where there is gold that will not amalgamate, cocoa matting is the better. Considerations of convenience in cleaning up the gold-saving areas often govern the choice.

COSTS

Dredging costs in the United States did not vary materially from those of former years. Operations on a larger scale in Klondike have lowered expenses, but no work has yet been done in tropical South America with a first-class modern dredge so that no figures are available for comparison. It has been variously estimated, by competent authorities, that for an operation involving the dredging of about 1,000,000 cu.yd. per year, where transportation is not difficult, a working cost of 10 to 25c. per cu.yd. may be anticipated. To one familiar only with dredging in California and having no knowledge of the disadvantages of tropical environment, these figures will seem excessive; but until dredging is conducted on a considerable scale in the torrid zone, it will be advisable to allow a working cost of not less than 10c. per cu.yd. as the minimum figure.

SMALL DREDGES

The need of a small dredge for the exploitation of areas not suitable for a large dredge is recognized in some quarters. The tendency since the introduction of dredges in California has been to build larger dredges with larger buckets. To be sure there was a time after the installation of the first 5-cu.ft. close-connected bucket when several 3-cu.ft. close-connected bucket dredges were installed. This was because of constant difficulty with the first 5-cu.ft. close-connected bucket resulting from bad design and

weak construction. Recent practice has approved the use of larger buckets.

The small bucket has come into disfavor largely because it was used as at Oroville in ground that was essentially suitable to working with large buckets. There is a distinct demand for a small dredge suitable to work inconsiderable areas or on areas of such shape and irregularity as to make it difficult to manipulate a large machine. There is also the consideration of cost which is a vital one. A dredge with 5-cu.ft. buckets costs about \$100,000; a dredge with 2½-cu.ft. buckets should cost about \$30,000. The capacities of these dredges should be about as three to one.

The record of failures has given the small bucket a bad name that it does not merit. There are areas in the tropics where the small dredge can be used to good advantage. Its light weight makes transportation, installation and operation easy and cheap; high gold content will compensate for the small capacity. By its means shallow ground of inconsiderable total acreage can probably be made the basis of a company when the first cost alone of a large dredge would make final profit an impossibility.

The small dredge has a function as a means of prospecting ground preliminary to the installation of large dredges. Small dredges have been used in this way in but few instances. Stewart river, in Canada, was prospected by this means in 1903. The common way of prospecting is to use steam or hand drills and results can thus be attained that are reliable and detailed. Drilling is cheap by comparison and a large acreage can be drilled so as to get detailed information at a much lower figure than the first cost of the prospecting dredge. The sectionalized gold dredge for muleback transportation is yet to be designed. The small dredge naturally will be more easily arranged for such transportation than larger and heavier dredges.

Gold dredging has been conducted with an unusual confidence in the honesty of the men who work on the dredges. On only a few dredges are there devices to prevent theft of gold from the gold-saving areas. During 1908 it was found that considerable amounts of gold were being stolen from dredges in California. This incident will probably lead to the incorporation of devices to keep under lock that part of the gold-saving areas where most of the gold is caught. This can be done easily and it will be good practice on all dredges. Even if not necessary, such procedure will be no more than a good business precaution.

Another large merger of dredging companies was recently consummated in California. A total acreage equal to all of the dredging ground at Oroville was

included. It is expected that lower working cost will be attained than when operating under several corporations. Standardization of dredge machinery in size and design will be attempted and the merged interests will build their own dredges. Dredging is one kind of mining that is particularly amenable to merger.

The Rare Metals VII—Tungsten

BY CHARLES BASKERVILLE*

Tungsten is commonly associated with granite. It is not found free in nature, and its ores are not numerous. The tungsteniferous minerals are shown in the following table:

TUNGSTEN MINERALS.

	Tungstic Acid Content.
Scheelite, calcium tungstate.....	71-80%
(a) Cuproscheelite, see cuprotungstate.	
Wolframite, iron and manganese tungstate.....	76-80%
Hübnerite, manganese tungstate.....	74-78%
Stolzite, lead tungstate.....	73-77%
Ferrierite, ferrous tungstate.....	70%
Powellite, calcium molybdate.....	10-11%
Reinite, iron tungstate.....	10%
Raspite, lead tungstate.....	49%
Tungstite, tungsten trioxide.....	100%
(b) Wolframite, tungsten trioxide.....	100%
(c) Meymacite, hydrated tungstic oxide.....	71-75%
(c) Cuprotungstate, copper tungstate.....	56%
Copper and calcium tungstate is also called cuprotungstate.	

Tungsten and tungstates are prepared from scheelite, wolframite and hübnerite. Tungsten is used quite extensively in the manufacture of steel for special purposes. Alloyed with steel, either by itself or with molybdenum and chromium, a product is obtained which possesses great toughness and ability to resist shock. This grade of steel is employed for high-speed tools, armor plate, projectiles, car springs, etc. Special alloys with aluminum, copper and various other metals have been prepared. An alloy of copper and aluminum containing tungsten possesses great strength and toughness. Tungsten is now utilized in manufacturing filaments for electric lamps; such lamps give good light, have low power factors and are less expensive to manufacture than the Cooper-Hewitt and Nernst lamps. Sodium tungstate is used as a mordant in dyeing, for rendering materials non-inflammable, as a decolorizing agent for acetates, and as a decorticator in preparing raw fibers for manufacturing. Sodium and potassium tungstates are employed in the production of "Magenta bronze" and "Saffron bronze," respectively; a mixture of these bronzes yields a violet pigment. Tungsten trioxide is used as an oil and water color, and in the manufacture of a yellow and blue pigment.

The demand and prices for tungsten are strong.

SHEELITE

This mineral is usually associated with crystalline rocks, and is found with cassiterite, topaz, fluorite, apatite, molybdenite, or wolframite, in quartz, and associated with gold. Molybdenum is often present and may replace a considerable amount of the tungsten. Didymium, cerium, lanthanum, and tantalum may also be present. It is found in this country in Connecticut, Massachusetts, North Carolina, Nevada, Idaho, Colorado, Montana and California.

Scheelite occurs in heavy brownish white or white masses, square pyramids, and in crusts of yellowish or brown crystals. It is a brittle mineral, having a vitreous luster inclining to adamantine, and may be found in a variety of colors—white, pale yellow, yellowish white, brown, green, or red; it is sometimes almost orange yellow. The streak is white; the hardness is 4.5-5.0, and the specific gravity is 5.9-6.1.

Scheelite fuses before the blowpipe with difficulty; the edges of the mineral fuse under prolonged treatment to a semi-transparent glass, not coloring the flame. It is soluble in borax in the oxidizing flame, forming a clear glass, which soon becomes milk white and crystalline. With salt of phosphorus, it dissolves easily in the oxidizing flame to a clear bead which becomes deep blue in the reducing flame from the formation of tungsten dioxide. Varieties containing iron give a brownish glass in the reducing flame, so they require to be treated on charcoal with tin before the blue color appears. The blue salt of phosphorus bead dissolves in dilute hydrochloric acid to form a deep blue solution, especially if metallic tin is added. When scheelite is pulverized and digested in a test tube with hydrochloric acid, the tungstic acid separates as a yellow powder; upon adding a piece of tin, the whole solution is colored blue. Scheelite is also decomposed in nitric acid.

Scheelite is distinguished from other non-metallic minerals by its weight and behavior before the blow pipe, especially in salt of phosphorus.

Cuproscheelite fuses before the blowpipe to a black glass, coloring the flame an intense green. With the fluxes, it gives characteristic tungsten reactions, and dissolves in hydrochloric acid with the separation of tungsten trioxide.

WOLFRAMITE

Wolframite is a frequent companion of tin ores, the cassiterite and the tungsten minerals having developed in much the same way. In some tin mines wolframite is an annoying impurity. It is also often associated with quartz, native bismuth, scheelite, pyrite, galena and sphalerite. This mineral is found in this country in Connecticut, Maine, North Carolina, Missouri and Nevada. Wolframite occurs in

heavy dark-gray to black sub-metallic crystals, orthorhombic, and also in coarse divergent columnar and granular masses. It is a brittle mineral with an uneven fracture and sub-metallic luster, and is generally of a dark brown to black in color. The streak is greenish gray to black; the hardness is 5-5.5; and the specific gravity is 7.2-7.55. Sometimes wolframite is feebly magnetic. It sometimes occurs altered to scheelite.

Wolframite fuses easily before the blowpipe to a globule, which has a crystalline surface and is magnetic. With salt of phosphorus it gives a reddish yellow glass while hot, which is paler on cooling; in the reducing flame, this glass becomes dark red and opaque. If this bead is pulverized and dissolved in dilute hydrochloric acid with the addition of tin, a blue solution is produced. With borax, a clear glass is produced in the oxidizing flame, and the iron or manganese reaction predominates. Wolframite fuses to a bluish-green manganate with soda and niter. It is decomposed by aqua regia with the separation of tungstic acid as a yellow powder, and is partially soluble in hydrochloric acid. The latter solution becomes intensely blue upon the addition of metallic zinc or tin. Wolframite is distinguished from titanite by its fusibility and deportment with salt of phosphorus.

HÜBNERITE

This mineral is abundant at Osceola, Nevada, with some scheelite, in veins of white quartz in a porphyritic granite. The tungsten deposits of the Dragon mountains, Arizona, are of similar character. It is also found in Colorado, Montana and New Mexico.

Hübnerite is found usually in bladed forms, rarely in distinct crystals. The color is brownish red to hair brown to nearly black, and the streak is greenish gray to yellowish brown. It is less fusible than wolframite and with the fluxes gives manganese and tungstic acid reactions.

Mining and milling costs per ton of ore crushed at the Simmer & Jack East property, South Africa, for the fiscal year ending in 1908 were: Mining, 10s. 6.224d.; pumping, 4.067d.; sorting and crushing, 4.487d.; transport of ore, 6.161d.; milling, 1s. 8.105d.; cyaniding, 1s. 0.756d.; slime expense, 4.977d.; general charges, 1s. 4.496d.; total, 16s. 3.365d.; redemption of development, 3s.; grand total, 19s. 3.365d. per ton of ore crushed. During the year 200 stamps ran 334.27 days and crushed 400,760 tons, or 5,995 tons per stamp per day. The ore milled assayed 5.942 dwt. per ton. The total saving was 92.09 per cent., 56.82 per cent., being saved by amalgamation. The tonnage mined was 464,395; of this 13,696 per cent. was sorted out as waste rock.

Slag Car Used at the Cananea Smelting Works

The Cast-steel Bowl Has a Capacity of 45 Tons and Is Held Rigidly Upright by Means of Steel Spring Latches upon Its Truck

BY CHARLES F. SHELBY*

The Cananea Consolidated Copper Company has developed a new slag car especially adapted for use in smelting plants where the tonnage to be handled is large and the available head room is limited. The car, which is shown in the accompanying illustrations, has a capacity

Over all the length of the slag car is 13 ft. 7 in., the wheel base being 8 ft. The bowl casting is 9 ft. 10 in. long; 5 ft. 2 in. wide and $39\frac{1}{2}$ in. high. The thickness of the steel at the bottom of the bowl is 3 in. and at the sides $2\frac{1}{2}$ in. The trunnion shafts are of wrought steel $3\frac{3}{4}$

center with a $\frac{3}{4}$ -in. plate and near the ends by the rail frames upon which the bowl rocks. Upon this body are mounted the draw-heads and the bearings for the wheels. The truck is suspended below the axles of the 24-in. wheels by means of U-bolts, which secure the bearing boxes to the frame. The wheels are of manganese steel, which seems to stand up exceptionally well under the severe conditions of the work. The truck is built for a 2-ft. 11-in. gage track.

The Hyatt roller bearings, shown in detail in the accompanying illustrations have, with the design employed, practically eliminated all trouble due to failure of truck bearings. The rollers are helical coils of tempered steel, having sufficient spring to eliminate much of the unnecessary friction due to strains. The strenuous duty required of the bearings of these large slag cars is particularly severe because of the heat to which all parts are subjected. The ordinary means of lubrication, the box bearing with oil

NEW SLAG CAR, CANANEA CONSOLIDATED COPPER COMPANY

of 45 cu.ft.; one train crew with six of these pots easily handles 1000 tons of slag per day. There are larger slag cars in use, but in designing the pot here illustrated, all the best features of the many different cars employed for handling large quantities of slag seem to have been combined.

The bowl is of Midvale cast steel and the trunnions are so placed that the pot is "bottom heavy" when empty and "top heavy" when full. The pot is held rigidly in an upright position on the carrying truck by means of two spring latches, consisting of flat bars of spring steel $\frac{3}{8}$ in. thick attached at one end to the trunnion face and the free ends engaging catches on the frame of the carrying truck. There are two of these latches, one at each end of the pot, and the respective catches are on opposite sides of the truck frame. A special tool is used to dump the bowl; it is called the spring-release lever, and is formed so as to grasp the loose end of the spring latch; a long handle of $1\frac{1}{2}$ -in. pipe enables the operator to spring the latch at one end of the truck free from its catch and to start the bowl from its center of equilibrium. The pot then rolls over on its rocker runners and dumps its contents automatically.

*Superintendent, reduction division, Cananea Consolidated Copper Company, Cananea, Sonora, Mexico.

HYATT ROLLER BEARING, CANANEA SLAG CAR

in. diameter and are attached to the body of the bowl by means of 2-in. keys.

Both the body frame of the truck and the frames upon which the bowl rocks, are constructed of 75-lb. rails. The rocker frames do not rest directly upon the main frame, but are elevated above it upon 7-in. cast-iron chairs. The pot does not swing in trunnion bearings, but rocks upon cast-iron rockers, or segments of wheels, provided with tread and flanges.

The body of the truck is a bent-rail frame with rounded ends, braced at the

cellar and waste, usually fails under these conditions. The Hyatt bearings used in this Cananea car eliminate practically all of these difficulties.

As a general rule, air-courses should always have as large an area as possible; this reduces the rubbing surface per square foot of section.

The Broken Hill Proprietary Company is going to install a baghouse in connection with its smeltery at Port Pirie.

The London Tin Market in 1908

SPECIAL CORRESPONDENCE

January started with an advance of 25s. per ton, bringing the price of three months' warrants up to £122. This was inspired by news of unexpectedly small shipments from the Straits, coupled with a reduction in the English bank rate of interest. Eastern and other sellers were alert to profit by the enhanced values, and bears followed their lead, whereby prices were temporarily depressed to £121 5s. for cash warrants, and £122 5s. for three months. On Jan. 9 considerable activity developed in consequence of improved American demand coinciding with the withdrawal of Eastern sellers. Further strength was indirectly imparted by the improved market for copper, until—on Jan. 15—£125 15s. was paid for cash warrants, and £126 10s. for three months, at which point the movement spent itself and the market lacked support. The relapse, however, was of short duration and was more than recovered when it became known that large American purchases had been made in the East, whereby bears were prompted to cover their recent sales. Later reports of heavy shipments from the East indicated unfavorable statistics, and the market was subject to some manipulation in view of the approaching Banka auction. Prices were thereby forced down to £122 10s. and £123 5s., respectively. This reduction, however, attracted some attention, particularly in America where stocks had run low. Moreover, the Banka sale produced the respectable average equivalent of £122 10s., whereupon sellers held back and prices moved up, closing at £124 5s. for cash, and £125 for three months.

In February the opening coincided with the Chinese new-year holiday, and afforded opportunity for operating on the bull side, whereby values were sharply raised, three months' warrants touching £131 on Feb. 5. Bears covered their commitments eagerly, and consumers bought freely, the turnover of the first week amounting to 3900 tons. Trade prospects, however, were not encouraging, and caution was inspired by the prospect of increased supplies. There was a speedy relapse which, on Feb. 18, caused cash warrants to change hands at £126. During that period the market was active, but irregular and confused, with occasional rallies due to the bull party controlling most of the supply and thereby forcing bears to cover their sales. Thereafter speculative interest subsided and business was restricted. Eastern holders refused to follow the downward trend, and as offers became scarcer the market improved, being further strengthened by the improved aspect of copper as well as by

an increased demand from America. Cash warrants rose at one time to £132, but the demand for prompt supplies was soon satisfied, and the market lacked support beyond what was afforded by bears covering. There was, moreover, assured evidence of ample supply. The closing prices were £129 10s. for cash, and £129 for three months onward.

March was an eventful month, opening with a fall of 30s. to £129 10s. for cash warrants, and £127 10s. for three months; the fall being induced by unfavorable statistics. On March 4 it was announced that the Dutch Government had revoked its recent decision to augment the sales of Banka by 1500 tons during 1908, so that the year's supply would be approximately the same as last. This announcement completely altered the tone of the market, and bears rushed in to cover their commitments, thereby raising prices to £136 10s. and £132 10s., respectively. This, however, was too sudden to last, and demand for early delivery was freely met by bull speculators and by Eastern holders. The volume of business during the first week was about 4000 tons, and prices closed at £133 10s. and £130 5s., respectively. On the resumption of business a further advance was made, due partly to purchases of forward metal by Chinese operators, and the market was practically controlled by the bull party for the rest of the month. Cash warrants were scarce, but the diminished American demand obviated serious trouble, and consumers generally were careful to buy only from hand to mouth. Some little relapse occurred during the third week when Eastern dealers sold freely, thereby depressing the cash price from £140 to £137 15s.; but skillful manipulation followed, carrying prices up until—on March 25—£147 was paid for cash, and £144 10s. for three months' delivery. On that day the Banka auction disposed of 1870 tons at the average equivalent of £147. Again followed a reaction due to realization of profits and withdrawal of support, and the fourth week closed at £143 10s. and £142, respectively. Excitement was engendered by a successful raid on the bear party, resulting in an advance to £145 10s. and £144 10s., respectively, fluctuations being very sharp. Final quotations were £144 5s. for cash, and £143 for three months.

April opened under more normal conditions than had lately prevailed, the excitement having greatly subsided. Eastern operators were ready sellers, and European holders liquidated hurriedly, thereby lowering the three months' price at the outset to £139 10s. At this juncture American and other buyers came in with good orders for consumption, and statistics of supply were regarded as favorable. Prices advanced in two days to £145 5s. cash, and £143 15s. three months, followed by a further advance of 15s. on April 6. This rapid advance brought out sellers who met demand freely, a sharp bear at-

tack being followed by pronounced weakness which brought down values to £141 10s. and £140 10s. on April 7. Another two days brought about a recovery to £145 and £143 5s., respectively, due to the support of leading interests. This again was followed on April 13 by a relapse of £2 15s., which in turn gave place to a sharp recovery on the news of a strike at the smelting works at Singapore. On the whole the market was erratic and subject to incessant manipulation in Europe and America. High-water mark was reached on April 23, when values stood £145 and £143 15s., respectively. Further fluctuations followed, business being mostly speculative; and closing prices were £143 for cash warrants and £142 for three months.

May opened with cash warrants at £142 5s., and three months at £141 10s. Shipments from the East were small, and statistics showed a decrease of 2493 tons in all; but the market was unresponsive, and prices dropped under pressure of realizations until—on May 13—the figures stood at £133 and £132, respectively. At this point short sales were briskly covered and some speculative purchases ensued. May and June supplies were found to be under strong control, and prices advanced in consequence to £137 15s. on May 19. On the following day prices broke sharply under forced realizations and general selling pressure until—on May 28—cash warrants changed hands at £126 5s., and three months at £125 10s.; the bull party being powerless to arrest the decline in face of enormous shipments from the Straits—estimated at 6800 tons for the month. The Banka sale in Amsterdam on May 26 realized the average equivalent of £133 10s. Throughout the month the consumptive demand was unimportant as compared with the speculative turnover. Only at the close of the month was some improvement effected, when a sharp rally carried values to £129 5s. and £128 5s., respectively.

June revealed an increase of 2731 tons in the stocks during the previous month, and prospect of heavy shipments from the Straits. The market opened weak, with heavy liquidations by tired holders. The cash and three months prices touched £126 15s. and £125 10s., respectively, but improved in sympathy with other markets and with some renewal of speculation. It was not until June 11 that any decided improvement was manifest, when Eastern offerings were reduced and three months' warrants were commanding a premium. On that day the cash and three months' prices closed at £129 2s. 6d. and £129 17s. 6d., respectively. Business, however, was almost entirely professional and lacked the support of genuine trade. American demand was conspicuously lacking, manufacturers being amply supplied. The rest of the month saw declining values and restricted business, the market

being sensitive to the frequent realizations by importers. There were feeble rallies as offers subsidized and operators tried to support the market, but the close was featureless and dull; cash warrants being quoted £125, with £126 2s. 6d. for three months.

July looked unpromising at the outset, consumptive demand being restricted and Eastern holders selling freely. Statistics, however, revealed a decrease of 1288 tons, whereupon bears took advantage of reduced prices to cover their commitments, and the market improved to £125 and £126 5s. At the advanced prices importers and Eastern sellers were for a time quite ready to meet the demand, but the market displayed considerable power of absorption, even at a rise of £2 on July 8. Thereupon bears became alarmed and hastened to cover, while demand set in from all sides. On the following day an advance of no less than £5 per ton was registered, and the advance culminated on July 10 when £133 15s. was paid for three months. Again a temporary reaction followed, dominated for some days, it being manifest that the movement was purely speculative and unwarranted by the conditions of the trade. Prices gradually fell back to £129 and £130 respectively, when speculators resumed buying and absorbed all offerings at advancing prices until, on July 16, a price of £135 was paid for three months'. Again a temporary reaction followed, induced by realization of recent purchases from the East; but by this time the notable advance in the share market had set much speculation in motion, and brokers were able to induce clients to take an active interest in metals. Strong buying ensued, in which consumers participated, whereby three months' warrants were raised to £140 on July 23. A healthy reaction followed, induced by Eastern and other sellers, as well as by the approaching Banka auction. When it became known that the latter had resulted in sale of 1800 tons as high as £142 speculation revived, and three months' warrants rose from £137 10s. to £139 15s. Statistics at the end of the month showed an increase of about 1600 tons. The consumptive industries appeared well employed, though the American tinplate trade left something to be desired. Speculative purchases sufficed to counteract the liberal offers of holders and of bears, and the month closed with cash warrants at £138 10s., with £139 15s. for three months'.

August opened, after the statutory holiday, and in the absence of several prominent operators, with a decline to £136 10s. cash, and £138 for three months, due to bear pressure which, however, failed to dislodge any important quantity. The lower level rather attracted speculative purchasers, resulting in improved values and followed by moderate consumptive buying. Eastern holders showed enough reserve to harden the market until £140 was paid for distant delivery. This figure

prompted realizations which, however, were well absorbed; while the continued firmness of Eastern sellers kept prices fairly steady until Aug. 12, when it became known that shipments from the Straits during the first 10 days of August amounted to the large total of 3000 tons. Thereupon selling pressure ensued which, for a while, was counteracted by the uplifting of fairly large quantities falling due; whereby the value of cash warrants was relatively enhanced and the contango reduced to 5s. Amid numerous fluctuations weakness predominated, and the second week closed at £135 12s. 6d. and £136 respectively. The third week opened with a break of nearly £4, caused mainly by continued heavy shipments from the East, both of current production and accumulated stock. There was an active business at the reduced prices, and some recovery in values; but bearish sentiment prevailed, and the improvement was partly lost. The fourth week opened still lower, due to fears inspired of further increase in the Eastern supply; and the lowest was touched on Aug. 25 when heavy realizations and bear selling combined to bring cash warrants down to 130 15s. and three months to £131 10s. Shipments, however, were found to be less than had been expected, and a recovery of almost £3 ensued but was not fully maintained. The close was dull in the absence of consumptive demand, with cash warrants at £132 7s. 6d., and three months £133 2s. 6d.

September found the market weak at the outset for lack of leading bull support, whereby the recent improvement was wiped out. At £131 15s. buyers of three months' warrants came forward, encouraged by the absence of offers from the East, and speculative interest broadened until £133 10s. was reached; from which point values receded to £132 10s. in sympathy with other markets. The second week opened strongly on the continued reserve of Eastern holders, and three months' warrants advanced to £133. American consumers gave the market no support and speculation subsided at this point, whereby holders were tempted to realize, more especially as Eastern offers became more frequent. Fluctuations were mostly downward until Sept. 21, when cash warrants stood at £130, and three months' at £131 7s. 6d.; from which point a sharp rally ensued, prompted by renewal of American demand. At the Rotterdam auction on Sept. 24 about 1800 tons Banka were sold at the average equivalent of £133 2s. 6d. Statistics at the end of the month disclosed large supplies, but these were disregarded in face of large demand, both speculative and consumptive. Closing values were £134 for cash warrants, and £135 10s. for three months.

October opened with a weak market, influenced by increased supplies and the prospect of an increased quantity of Banka

to be auctioned in the next year. Fluctuations were numerous and induced by improved American demand, alternating with heavy realizations of speculative holdings. The lowest was touched on Oct. 13, when three months' warrants changed hands at £133 10s. Eastern sellers were not pressing, and American consumers bought but sparingly; but prominent operators judged the movement favorable for an improvement in sympathy with other commodities, and offerings were plentifully absorbed. Thereafter, with numerous fluctuations, the tendency was upward; and the month closed with cash warrants at £136 5s., and three months £137 15s. per ton.

November statistics were more favorable than had been anticipated, and prompted a concerted bull movement which gathered strength after the result of the American presidential election was known. Opening at £137 10s. for cash, and £139 for three months, prices were carried—with occasional relapses due to speculative realizations—up to £142 5s. and £144, respectively, after which the buying power was insufficient to arrest the decline caused by persistent realization of old holdings; and values drifted down to £135 5s. and £137 5s. on Nov. 16. America sent substantial buying orders at each decline, pointing thereby to an improved statistical position ultimately in spite of heavy shipments advised from the East. Values again improved to £137 and £139, respectively on Nov. 19, relapsed again to the extent of 30s.—at which decline large quantities were marketed—and recovered to £137 7s. 6d. and £139 7s. 6d. on Nov. 25. Thereafter depression ensued on unfavorable statistics and heavy shipments from the Straits. At the Banka auction in Amsterdam on Nov. 26 a total of 1870 tons was sold at the average equivalent of about £140. The month closed with a dull market at £135 2s. 6d. cash, and £136 15s. three months.

In December persistent selling, chiefly by Eastern holders, caused weakness from the outset. The consequent decline in values was temporarily arrested, but proceeded farther as a result of bear selling. Reduced prices attracted buyers, and large quantities were absorbed, sometimes causing a temporary rally; but at each improvement in values sellers competed keenly and renewed the depression until—on Dec. 14—£130 10s. was accepted for cash warrants, and £132 5s. for three months. At this point the market was steadied by a fair consumptive demand—more from America than from Europe—and rallied somewhat; but heavy shipments from the East, coupled with readiness of Eastern holders to sell, checked further improvement, and values remained for several days round about £132 and £133 10s., respectively; closing weak at £131 7s. 6d. for cash and £133 for forward tin.

The London Spelter Market in 1908

SPECIAL CORRESPONDENCE

January opened with some activity due to improved Indian demand for yellow metal, and in a lesser degree to active buying for galvanizing. Competition, however, was too keen to allow of any improvement in price until Jan. 13, when it became known that the leading European producers were convening a meeting to discuss a policy of curtailment in production. Speculators were alert to forestall the improvement thus foreshadowed, and a large business developed in spelter and also in sheet zinc. Some revival of demand for galvanized iron also stimulated the upward movement which culminated on Jan. 20 with £21 7s. 6d. paid for ordinary brands. Thereafter values fell away under pressure of realizations by speculators, producers remaining firm, however, and holding little unsold, while the continental inland transport was impeded by ice and so tended to reduce available supplies. Closing prices were £20 12s. 6d. per ton for ordinary brands, and £21 7s. 6d. for Silesian specials.

In February uncertainty prevailed at the opening concerning the projected convention of the German producers, and some little weakening of prices resulted; but offerings were small and demand fair, so that the relapse was insignificant and transient. It soon became known that the convention was definitely established, and the market firmed up in consequence to £21 17s. 6d. for ordinary brands. Consumers and dealers alike bought freely, some improvement in the galvanizing trade serving as an additional stimulus, as also a large business in sheet zinc. The advanced price induced some realizations about the middle of the month; and demand being now satisfied, prices were allowed to drift downward while consumers held off awaiting the result of negotiations for extending the convention so as to include Belgian and other continental producers. The decline was gradual during the remainder of the month, closing prices being £21 2s. 6d. for ordinary brands, and £22 7s. 6d. for specials.

March was singularly devoid of interest, and fluctuations were unimportant. Producers for the most part had sold well and were holding aloof. On the other hand consumers were slow to purchase, and their few orders were keenly competed for by dealers. Opening at £21 for ordinary brands, it at once relapsed 2s. 6d. per ton, and thereat remained for eight days. Demand then revived and caused a recovery of 5s., which ruled up to March 10, when a slight relapse was induced by pressure of second-hand parcels. At the end of the month large transactions with continental producers imparted renewed

strength to the market, which closed with ordinary brands at £21 2s. 6d., with £21 17s. 6d. for specials.

April opened with an active market, stimulated by many consumers' inquiries. Ordinary brands, quoted at £21 2s. 6d. @ £21 5s., advanced 7s. 6d. per ton until April 8, after which inquiry dwindled chiefly as a result of the disappointing quietness prevailing at the quarterly meeting of the Iron Trades in Birmingham. On the Continent a large business was done extending into September, and foreign producers were consequently firm in their quotations, but numerous speculative parcels were placed on the London market at constantly receding prices, consumers remaining very apathetic. The rest of the month saw a slow but persistent decline in prices, which closed with ordinary brands from £20 17s. 6d. @ £21 2s. 6d., and Silesian specials from £21 10s. to £20 15s.

May opened with a fall of 5s. per ton, due to dwindling demand and the keen competition for the few orders which consumers had to place. For a week or so the market was steady in view of producers' firmness and the inability of dealers to cover their speculative sales without loss. The next feature was a sudden drop to £19 17s. 6d. which was accepted for a speculative parcel thrust upon an unsupported market. Sellers continued to offer at a fraction over this figure for some 10 days, but the slackness of trade was too general and persistent to avert a further fall to £19 12s. 6d. The close was a trifle firmer, with ordinary brands from £19 15s. to £20, and Silesian specials from £20 to £20 5s.

June found the market destitute of support, consumers being apathetic, and dealers keen in competing for the few orders obtainable. The prolonged stagnation caused continental producers to become impatient, and their quotations eased off in consequence. The protracted and unfruitful negotiations in regard to the projected Producers' convention also tended to depress the market. Price of ordinary brands opened at 19 15s. and fell gradually but persistently during the month to £18 7s. 6d., closing thereat, Silesian specials being offered from £19 5s. to £19 10s. per ton.

July found a stagnant market at the outset, values being depressed by forced sales of arriving parcels. These were in most cases marketed at £18. Early in the month, however, considerable speculation developed in metals generally, wherein spelter participated to a moderate extent. The movement originated on the Continent, where operators turned to London as the cheapest market to buy in. The consequent improvement in values was more manifest as regards forward delivery than for prompt. Consumers followed the lead thus given, and additional firmness was imparted by increasing business in sheet zinc at advancing prices. The highest price recorded was £20 paid on

July 20 for December delivery; but at the same time prices were very erratic for early delivery, and the trade requirements were not sufficient to impart steadiness. The market thereafter was neglected, and prices fell away toward the close, when ordinary brands were quoted £19, and specials £19 7s. 6d.

August opened quietly, the consuming industries being slack and not disposed to support the market. Early in the month, however, good business was reported from Germany, and improved reports from America helped to raise values. Speculative orders from abroad strengthened the upward movement, and consumptive demand followed. The close was firm at £19 5s. for ordinary brands, and £19 15s. for specials, with indication of recovery.

In September, business, though restricted, was fairly steady throughout the month, and fluctuations in price were unimportant. The gradual improvement in iron and steel was reflected in improved demand for galvanized wares, while sheet zinc was in increased request and helped to maintain prices of spelter. Producers, having sold well, were at no time pressing in their offers, and consumers were encouraged to cover requirements in view of the approach of winter. Ordinary brands opened at about £19 7s. 6d., advanced gradually and touched £19 17s. 6d. once or twice, and closed at £19 15s., with from £20 5s. to £20 10s. for specials.

October saw a steady trade throughout; consumers found the ruling prices reasonable and the prospects of trade more encouraging, and a fair volume of business resulted. Buyers were keen to obtain early delivery of what they bought, which is always an indication of improving trade, and this proved to be the case as the month advanced. Producers were firm in their quotations, and orders were taken mostly by dealers whose concessions caused a trifling relapse in prices down to Oct. 21, when £19 12s. 6d. was accepted for ordinary brands. Thereafter the market strengthened with expanding business, and closed at £19 17s. 6d. @ £20 for ordinary brands, and £20 5s. @ £20 10s. for specials.

November found the London market active on trade demand coupled with renewed speculative interest in the article. Opening at £20 for ordinary brands, the price steadily advanced, and the month closed with ordinaries at £21 7s. 6d. @ £21 10s., and £21 15s. @ £22 for specials.

December opened with some welcome activity in the consuming branches, and with no plentiful supply; business extending in some cases well into the next year. Early in the month, however, demand was satisfied, and further business was checked by the approach of the holiday season and stock-taking. Some speculative holdings, pressed upon an unsupported market, caused a gradual relapse to about £20 12s. 6d. toward the middle of the month; but producers were in nowise disposed to fol-

low the decline, and their firmness caused a gradual improvement. The closing quotations were £21 for good ordinaries and £21 5s. for specials.

Conveyer System for Disposing of Waste

By EDWIN HIGGINS

Since writing the article on "Stripping Clinton Iron Ore in New York State" I have secured additional information regarding the conveyer used at Ontario Center for disposing of waste material. Sufficient interest attaches to this machine, on account of adaptability to the

are of cast steel especially designed for this service, and in order to reduce vibration no springs are used, although the journal boxes are the usual type with brasses and oil reservoirs.

On the center of the platform is a superstructure of two trusses with an inclination of 26 deg. on the upper plane; two 6-yd. cars travel on this plane. These cars are handled separately by a double friction-drum steam hoist situated on the platform on one side of the incline. The hoist is a 12½x15 double-cylinder skeleton machine rated at 75 h.p., and is supplied with steam from a 100-h.p. boiler on the opposite side of the incline.

OPERATION

The loaded cars are each hauled to the

To operate the conveyer with reasonable speed a force of three men is required, viz., a fireman, engineer, and brakeman. The engineer handles the throttle and frictions and hauls the cars to the top, and as soon as they are dumped he instantly releases the drum, which is then controlled by the band brake operated by the brakeman. In this way each car is entirely independent, and can be handled at full speed in either direction without reference to the condition of the other car. In case of needed repairs one car can be operated alone, thus giving at least one-half service.

In addition to the men required on the conveyer a track gang is necessary; this gang prepares the track in advance of the machine. The track has four 100-lb. rails

DOBBIE CONVEYER. ONE SKIP IN POSITION FOR LOADING; THE OTHER DUMPING

work and the rapidity with which it handles the waste, to warrant the following description:

CONSTRUCTION

The conveyer, shown in the accompanying illustration, consists of a platform 36x40 ft., mounted on four 4-wheel swivel trucks which have 33-in. wheels on standard 5½x10-in. journals. The truck frames

upper end of the incline by a single rope, where they run on tracks which cause the rear end to raise until the car is in a vertical position. The dumping position of the cars is 70 ft. above the ground and 68 ft. beyond the side of the platform. The total travel of the cars is 130 ft., and as long as the shovel can fill the cars a round trip is easily made in 30 seconds. This speed, however, is not maintained on account of delays common to steam-shovel work.

at standard gage and is merely placed on the ground approximately level, but without any ballast.

To move the conveyer, wire-rope blocks with five parts of 5½-in. cable are used. On the end of the cable is bent a manila rope which is wrapped around the winch heads on the drum shafts. The entire machine, which was built by the Dobbie Foundry and Machine Company, of Niagara Falls, N. Y., weighs approximately 140 tons.

Work of United States Geological Survey in 1908

The field work of the United States Geological Survey in 1908 shows great variety and range, as it included investigations of practically all the natural resources and their dependent industries, and extended over the entire country.

Beginning in 1879 with the appropriation of \$100,000 for the classification of the public lands and the examination of the geologic structure, mineral resources, and products of the public domain, the duties imposed by Congress on the Survey and the appropriations made for its work have steadily increased until now its field of operations covers the whole country including Alaska. The appropriations for 1908 amounted to \$1,782,770, and over 150 parties were in the field. The work ranged from that of the explorer and geographer making reconnaissance surveys in interior Alaska to that of the coal-mining engineer carrying on experimental gas and coal-dust explosions, for the purpose of saving human life, and to that of the geologist determining the presence of coal, water, or petroleum thousands of feet beneath the earth's surface.

GEOLOGIC INVESTIGATIONS

The primary work of the Survey is to make a geologic map of the United States. Geologists have been at work during the year in all the coastal plain States, from Maryland to Texas inclusive, investigating the distribution of the rock formations and correlating the underground water-bearing beds. The States of Maryland, Virginia, North Carolina, South Carolina, Georgia and Florida have cooperated with the Federal Survey in this work, paying one-half the cost; Louisiana has similarly cooperated in the investigation of the new Caddo oilfield in that State. In Pennsylvania, detailed studies of the coal beds and the oilfields in the vicinity of Pittsburgh and farther up the Allegheny river were made in cooperation with the State; similar geologic work was also carried on south of Altoona and east of the Allegheny front. Indiana also cooperated with the Survey, and advantage was taken of the thousands of recent drillings and of the data procured in many new mines to revise the old State report on this coal field. In Illinois detailed investigations of the coal and oilfields was continued in cooperation with the State survey as in the past few years. About \$20,000 was contributed in 1908 by the various cooperating States for geologic work, the Federal survey furnishing a like amount.

WORK IN THE OILFIELDS

In the oil and gas surveys in Oklahoma the approximate elevations of all wells in the surveyed districts were obtained by running level lines. As one of the important objects of this work is to deter-

mine the structure of the oil-bearing sands and their relation to the surface and as the oil and gas operators understand the nature and purpose of these surveys, they willingly aided the work by furnishing drill records and other data. In the California oilfield important work has been done classifying public lands, and several temporary withdrawals have been made where oil land was being entered as agricultural land. In the Caddo oilfield in Louisiana, all the Government land has been withdrawn from entry pending an effort to stop the enormous waste of natural gas, estimated at 75,000,000 cu ft. per day.

Through the economic work of the geologists of the Survey it has become evident that one of the greatest needs of the petroleum industry is a general chemical examination, by uniform methods, of all the crude petroleum of the United States in order that the petroleum in one part of the country may be compared with those of another part. The importance of choosing standard methods of chemical examination for petroleum was seen from the first, so consultations have been held with the principal petroleum specialists of Europe and a system of examinations has been developed which is being practically applied as rapidly as possible.

PROMINENCE OF MINING GEOLOGY

Mining geology—the scientific study of metalliferous deposits—is now recognized as the basis of the highest type of mine development, so that the demand for Survey geologists to do this work is so great that it is not possible to satisfy it. During the season the Government mining geologists worked in several mining districts in northwestern and northeastern Nevada; in the Randsburg mining district in California; in southeastern Oregon and in the Bohemia district of that State (in connection with the work of the Forest Service); in the Frisco district, Utah; in the Caspar district, Wyoming; in the Breckenridge and the Lake City mining districts, Colorado; and in the district south of Dahlonega, Georgia. Reconnaissance were also made in the Frisco, Pioche, Cima, Hart, Rawhide and Aspen districts. Work was continued on the Shasta County, California, copper deposits; on the Leadville district; on the New Mexico mining district; and on the Joplin and Oklahoma districts.

CLASSIFYING AND VALUING COAL LANDS

The Survey had nearly 100 men engaged during the season in the geological examination, classification, and valuation of the great area of public coal land in the West. They classified 11,500,000 acres of coal land in Colorado, Montana, New Mexico, North Dakota, Oregon, Utah, Washington and Wyoming. The valuation of the coal deposits includes not only the determination of geologic conditions, but also physical tests of efficiency in the Sur-

vey testing plants. Reports presented to the Conservation Commission on the rapid exhaustion and exportation of phosphates have resulted in the withdrawal of the entire area of public phosphate land, pending legislation by Congress.

MINING AND GEOLOGIC WORK IN ALASKA

The work of the Alaskan division has embraced investigations of a varied character and has been widely distributed throughout the Territory. Reconnaissance, detailed geologic and topographic surveys and explorations were made as well as special investigations of the gold, copper, and coal deposits. In the placer districts data were collected on stream flow; some general stratigraphic and geologic studies were made; and statistics of mineral production and data on the progress of mining were collected.

Thirteen parties, including 23 technical men and 25 camp hands were engaged in Alaskan surveys and investigations. The field season for the different parties in 1908 varied greatly, but the work was carried on between March and November. Four parties were engaged in geologic work, four in both topographic and geologic surveys, and two in investigating water resources. The areas covered by geologic reconnaissance surveys (maps, 4 miles to the inch) embrace 4850 square miles, detailed geologic surveys (maps, 1 mile to the inch), 668 square miles. Topographic reconnaissance surveys (maps, 4 miles to the inch) were completed of 3975 square miles, and detailed topographic surveys (maps, 1 mile to the inch) of 427 miles. As a result, about 21 per cent. of the reconnaissance topographic base map of Alaska is completed, and about 17 per cent. of the reconnaissance geologic map. These results have been accomplished since 1898.

In the Yukon-Tanana region 21 gaging stations were maintained during 1908; these furnished data on the water resources of 4000 to 5000 square miles. In the Seward peninsula 32 gaging stations were maintained, yielding data on about 2000 square miles.

To consider the work geographically, two parties were in southeastern Alaska, two in the Copper and White River basins, one on Prince William sound, one on the Alaska peninsula, four in the Yukon basin, and three on Seward peninsula.

Among the important results of 1908 were the completion of detailed surveys of the two most important copper districts on Prince of Wales island; the finishing of the reconnaissance survey of copper-bearing areas of the Prince William sound and the Copper-White river regions; and the completion of the reconnaissance survey of the coal deposits in the Alaska peninsula region. The base map of the entire Yukon-Tanana region has been completed, and also the detailed geologic investigation of the Fairbanks placers.

Through this work much new information on the general geology and mineral resources of the Seward peninsula was obtained, while the stream-gaging work in both the Seward peninsula and Yukon-Tanana regions yielded important results on the water available for placer mining.

TWENTY-SEVEN THOUSAND SQUARE MILES MAPPED

The first step toward making a geologic map is a topographic survey; the topographic branch of the Survey is, therefore, one of its most active parts. During the last field season 26,994 square miles of topographic mapping was completed; 6024 square miles in the Atlantic division, 6069 square miles in the Central division, 3875 square miles in the Rocky mountain division, and 11,026 square miles in the Pacific division. The surveys included work in 32 States and Territories. Special drainage surveys were made in Minnesota, Mississippi and California. In Minnesota the special drainage survey of the ceded Chippewa Indian lands, authorized by Congress, was completed, 2385 square miles being mapped in 1908. The data will be used in making drainage plans by the Survey as directed by Congress. In Mississippi a topographic map of 1200 square miles of swamp land in the Yazoo delta was made in cooperation with the Tallahatchie Drainage Commission, which will use the data for drainage construction. This survey has been made on the especially large scale of 2000 ft. to the inch, with 5-ft. contour intervals and with 125 elevations established to the square mile. In California the work of mapping the Sacramento valley, including the tule swamps, progressed well; 1054 square miles were mapped with 5-ft. contour intervals on a special scale of 2 inches to the mile.

Notable sections surveyed in the Pacific division are the oil-belt region extending from Coalinga to Mount Hamilton, in California, where the surveyors are still in the field; the Crater Lake National park and the Eugene quadrangle in Oregon; the Carson Sink quadrangle, an area of 3688 square miles in Nevada including the larger part of the Truckee-Carson project of the Reclamation Service; and the Flagstaff quadrangle, Arizona.

In the Rocky mountain division, the Breckenridge Special quadrangle in Colorado, was mapped, and a tablet was set on the summit of Pikes Peak, correcting the mountain's elevation. In New Mexico, 25 miles of the Fort Bayard military reservation was mapped on a large scale with a 10-ft. contour interval. A survey was also made of the Fort Missoula reservation, on a scale of 4000 ft. to the inch with 5-ft. contours.

A large proportion of the topographic work has been done by the Survey in cooperation with States, which pay one-

half the cost of the work. The total amount so contributed by the various States is approximately \$100,000; the States contributing are California, Mississippi, Illinois, Iowa, Kentucky, Maine, Maryland, Michigan, Missouri, New York, Ohio, Oregon, Pennsylvania, West Virginia, North Carolina, and Virginia. In Mississippi the drainage commission, which is the agency of coöperation, is paying the bulk of the cost. Forest fires in various parts of the country interfered considerably with the map making, the Survey's loss in field work by reason of smoky conditions amounting to about \$10,000.

MINE EXPLOSIONS AND RESCUE WORK

While the National Conservation Commission and others have been educating the public to the fact that there are enormous avoidable losses in the natural resources of the United States, the Technologic branch of the Survey has been quietly demonstrating that many of these losses may be stopped. The investigations made have tended to show not only the waste of natural resources in the mining and consumption of coal, but also the terrible loss of life in this industry. A notable event in 1908 was the opening at Pittsburg, Penn., of the experiment station, established for the purpose of investigating the causes of mine disasters. This station had been in operation for several months before its formal opening early in December and the experiments made there have already shown that many mine disasters can be prevented. At this station, it has been demonstrated conclusively that coal dust is as dangerous an explosive as firedamp. The possibility of coal-dust explosions has been a mooted question among miners, and its solution will go a long way toward reducing fatal accidents in the mines. It has also been shown that many of the "safety" explosives are not safe. The Survey's purpose is to standardize these explosives, so that when a miner explodes a charge of powder he will have some definite idea of what it will do. This too cannot fail to result in a reduction of accidents, and it also means the saving of much coal, as the use of improper explosives makes a great deal of unnecessary slack and dust. An important feature of the experiment station is the gas-filled room where miners equipped with oxygen helmets are being trained in rescue work. Mine owners have been invited to send picked squads of their men to the testing station, where they are taught how to work with helmets. This should unquestionably result in a further saving of life.

UTILIZING FUEL WASTE

In trying to decrease the waste of coal, interesting experiments are being carried on at the Survey's fuel-testing plant at Pittsburg. This plant is now being successfully operated on "slack" coal cost-

ing 88c. per ton delivered and on "roof coal," which is usually left in the mines. These experiments show immense possibilities in the use of fuels and add a considerable amount to the usable coal reserve. The coals are burned in scientifically constructed furnaces, without smoke, and in this way the Survey is furnishing an object lesson to the entire country. Manufacturers and engineers are watching the experiments with keen interest, and in many plants improvements in the coal-burning apparatus are directly attributable to the Survey's pioneer work.

At the fuel-testing plant at Denver, Colo., investigations have proved that practically all the coals of the Rocky mountain fields, when they are washed and are properly treated in the process of coking, will produce coke that can be used for metallurgical purposes. This was not known and, in fact, was not believed before the Geological Survey took up these investigations. The big metallurgical interests were at that time sending East for their coke.

TESTING BUILDING MATERIALS

At the structural-materials laboratories at St. Louis, Mo., tests of the strength of the different materials of construction and of the fire-resisting qualities of these materials were continued throughout 1908 and the deductions therefrom given to the public. These tests indicate the possibility of so reducing the amount of material used in public buildings and structures made wholly or in part of reinforced concrete that the cost may be reduced to per cent.; for, owing to the present lack of knowledge of the behavior of concrete and of reinforced concrete, high factors of safety involving the use of excessive quantities of material are now necessary in designing structures of this material. The establishment of a fully equipped laboratory at Pittsburg for investigating the chemical and physical properties of clays and clay products has already proved to be of value to the Government in connection with its purchases of such materials.

The nominal strength of detonators, at least those used in Western Australia (E. A. Mann, chief inspector of explosives for that State, *Journ. Chamber Mines*, West Australia, July 31, 1908) is not rigidly adhered to in manufacture. Missed holes in mines, therefore, may be caused by the detonator cap, for probably the caps furnished in Western Australia, where explosives are rigidly examined, are of at least as good grade as those furnished elsewhere.

The Ural coal production for the first half of 1908 is given in the *Torg. Prom. Gazeta* as 24,577,014 poods against 21,158,845 poods in the same period of 1907.

The Turquoise Mining District, Arizona

BY JAMES M. PLATT*

The Turquoise mining district is nine miles south of Pearce, Arizona; as it is a highly mineralized area, the camp is rapidly coming into prominence as a future producer of copper. The geology of this part of Arizona has not been mapped, at least so far as I know; consequently I will roughly indicate the geological features of the vicinity. Starting from the granite of the Dragon mountains, about four miles west of the present active camp, and going east, the general order of occurrence of rocks is: Granite; quartz-porphyrates traversed by iron-stained quartz lodes and forming a belt about three miles wide; a range of hills about half a mile wide of rock locally called quartzite, but which I think is quartz-diorite; a limestone belt varying in thickness, but averaging about 1500 ft., in which are the Leadville and the old Great Western mines; a belt of quartzite or quartz-diorite, from 100 to 400 ft. wide; limestone of Carboniferous age about 1500 ft. wide; from there into the Sulphur Spring valley dioritic porphyries.

Taking the different belts in the same order I will describe the work done in each. The vein country (quartz) is entirely undeveloped, although located. In the main ridge of quartzite some turquoise has been developed. On the first quartzite-lime contact, large bodies of sulphide ore have been developed on the 200- and 300-ft. levels of the Leadville mine; most of this ore carries from 3 to 5 per cent. lead and some of it assays from 8 to 12 per cent. This is a stock company, having a capital stock of 600,000 shares of a par value of \$1. The stock is held almost entirely by local people, and has not been handled by any outside promoters. In the lime country east of the contact this company has also developed several small veins of galena. Adjoining the Leadville property on the south and on the same quartzite-lime contact is the old Great Western mine. This property has in the past produced over \$250,000 worth of sulphide and carbonate ore, all from above the 300-ft. level, but, during the last three or four years it has produced very little ore.

Next to the east in the first lime belt is the property recently bonded by Martin Costello to the Copper Queen Consolidated Mining Company for \$200,000. In this property good carbonate ore has been developed from a shaft 250 ft. deep; the mine is now being studied by the Copper Queen engineers.

On the next lime-quartzite contact the Calumet & Arizona Mining Company has

several claims bonded; in them it has developed large amounts of carbonate ore. The Great Western property extends to this contact, and some fine carbonate ore has been developed from that company's shaft. It is reported that the Calumet & Arizona company has taken over the Great Western property at a price of \$750,000, but I am unable to obtain exact information.

In the lime belt just east of this last contact there is a big "iron blowout," or gossan, covered by the Maid of Sunshine claim; under this gossan a large amount of carbonate ore has been developed. This claim together with its north extension is owned by the Leadville company, but has been bonded by them to the Calumet & Arizona company for \$200,000; \$10,000 being paid at the time of signing the option. South of the Maid of Sunshine and adjoining the Great Western property on the east are 20 or 25 claims in lime country with several good gossan capings. These have been bonded by D. W. Brown and his brothers, to the Copper Queen company for \$200,000.

Many other claims in the camp have been changing hands, and people are talking of town sites. There are several good locations available, but as yet almost everyone lives in a floored tent near the various operations. Many men come to the district seeking work, but few are put on. Development is being pushed by the three main companies, and at present all the ore comes from this development work, for all are waiting the advent of a railroad. A railroad can be easily built either from Pearce, whence a line runs to the Southern Pacific, or from Douglas, about 34 miles to the southeast. As is well known, the Copper Queen and Calumet & Arizona smelters are in Douglas, on the El Paso & Southwestern railroad. It, therefore, is more probable that a branch will be built from Douglas rather than from Pearce into the Turquoise district. This branch would be very easy of construction, as it would pass through a smooth valley, the only difficulty being to provide for drainage in the rainy season.

The name of this camp is in debate. The original locators stick for "Leadville," but the Calumet & Arizona company calls its little town "Courtland."

The Cement Industry in 1908

The following statement regarding conditions in the American portland cement industry during the year 1908 has been prepared by Edwin C. Eckel for the U. S. Geological Survey. Although detailed figures are not yet obtainable, an estimate based on the information available indicates that the production of portland cement in the United States was somewhat less than forty million barrels. This

compares as follows with the output of recent years: 1905, 35,246,812 bbl.; 1906, 46,463,424; 1907, 48,785,390; 1908 (estimated), 40,000,000.

The falling off from the 1907 output was heavy, and is particularly notable because it is the first decrease shown in any year by the American cement industry since its inception. The decrease was not uniformly distributed throughout the country, for New York, Pennsylvania and New Jersey will probably show the highest percentages of loss, while in some portions of the West and the Middle West the decrease was relatively slight.

During the year several small companies went into the hands of receivers and the financial stress also led to a change of control in a group of plants operating chiefly in the Pacific States. A fortunate effect of the depression was that it put a stop, temporarily, to the flotation of fraudulent or doubtful cement securities; though with improvement in general business conditions it is likely that promotion schemes will again be taken up on an even larger scale than before the depression.

The year 1909 opens with heavy stocks of cement on hand at most mills, but with good prospects for a steady, though slow, revival in the cement trade. It is unlikely that this revival will be sufficiently rapid to push mills to their capacity during the year, and it is, therefore, possible that the high record for output made in 1907 will remain unbroken for another year at least. The total maximum capacity of existing plants is now about 60,000,000 bbl. a year. Despite the business depression, or perhaps partly because of it, there were a number of important technical and industrial developments in the cement industry during 1908, and others are still pending.

C. O. Schmitt (*Journ. Chem., Met. and Min. So.*, of South Africa, July, 1908) suggests that at mines where, during part of the day, as for instance, when blowing out powder smoke between shifts, compressed air is used for ventilation, the low- and high-pressure cylinders should be arranged so that at such times each cylinder can exhaust directly into the air main. This would, in most cases, add 50 per cent. to the volume of air delivered into the main, and where a certain amount of air must be supplied the coal consumption would be reduced one-third. The air, as it passes through only one cylinder, would be less contaminated with oil.

The capacity of the De Bavay process plant at the North Broken Hill mine, New South Wales, according to *Aust. Min. Stand.*, June 3, 1908, is being increased to 1500 tons.

*Mining engineer, Tombstone, Arizona.

The South Lorraine Silver District, Ontario

A Partially Developed District Which Promises Future Importance;
Prospecting on 10 Claims Shows a Geology Similar to That of Cobalt

BY WILLIAM B. PHILLIPS*

The unsurveyed portion of Lorrain township, east and southeast of Cobalt, which is known as South Lorrain, is the scene of considerable activity. The district is best reached from Haileybury by boat on lake Temiskaming, but when navigation has closed it is accessible over the winter road from Haileybury, by way of the Green-Meehan, Martineau bay and the old mission. From Haileybury, by boat, the distance is about 22 miles, the trip occupying $2\frac{1}{2}$ to 3 hours. The landing place on the lake is known as Silver Center, near which the Government dock is being built, with promise of completion next summer. There is a private dock, a mile below, known as Maloney's.

From Maloney's there is a fair road into the heart of the new district, 4 miles west, and another road from the Government dock, or "666," as it is called. The country rises rapidly from the lake and reaches an elevation of 500 to 600 ft. above the lake in a distance of 4 miles.

GEOLOGY

Roughly speaking the new district is in the contact between the diabase (and gabbro) and the series known as Keewatin, the oldest recognized formation. The Keewatin here is characterized by the usual greenstones, quartzites and conglomerates that distinguish it in the Cobalt district proper, 20 to 25 miles northwest. On the lower road, from Maloney's, diabase and gabbro principally are seen, while on the upper road, from the Government dock and Sullivan's, the rocks are, for the most part, Keewatin. The line of contact runs between these two roads and may be seen near the properties known as the Williams, Keeley, Elkhart, Emerick, Haileybury Silver, etc., and generally to the west of Loon lake.

THE PRINCIPAL CLAIMS

Active work is now in progress on the following properties, all within $1\frac{1}{2}$ miles of each other: Jowsey (now known as the Keeley mine), Haileybury Silver, Keeley, Gibson, Ferner, Taylor, Nugget, Elkhart, Williams and Wettlaufer. The Keeley mine and the Haileybury Silver have about three or four cars of ore sacked and ready to ship. Excellent veins containing smaltite and native silver have also been exposed by trenching on the new Keeley property, west of the Keeley mine. The show place in the district is Wettlaufer's, where a beautiful vein in the diabase and gabbro was uncovered at

the bottom of a trench less than three feet deep. This vein is not as wide as the famous Lawson vein near Kerr lake, in the Cobalt district, nor exposed over as great a distance as the native silver vein on the La Rose property, but the fineness of the silver is said to exceed that of either of these localities. It is reported, but I am unable to quote the authority, that in general the quality of the silver from this new district is superior to that from the Cobalt district, and that less smaltite, cobaltite, niccolite, etc., are found. Whether this is true or not it is certain that a more beautiful sight than the Wettlaufer vein, or some of the Keeley and the Haileybury Silver ore would be hard to find.

In this district the silver occurs largely as flattened plates and sheets and appears to run into the wall rock. On either side of the calcite (or calcite and quartz) veins, the wall rock is distinctly worth saving, many of the planes of fracture showing plates of silver. Just prior to my visit a 900-oz. assay had been obtained from an open cut on the Haileybury Silver property and the material did not seem to be so rich, judging from a cursory examination. But a closer inspection showed that it was penetrated by fine plates of silver, very thin and crusted in appearance. These were distributed through the wall rock of Keewatin greenstone having a somewhat slaty structure; they were found not only along fracture planes, but even in the body of the rock itself and not always in any close association with calcite. On the West Keeley property the rock is also Keewatin and here some good specimens carried native silver in quartz.

In fact silver-bearing quartz is more prevalent in this district than in the Cobalt district proper and the association of this mineral with the silver is more pronounced. Some of the calcite and quartz veins carry galena and this is often barren of silver, as is also the pyrite and chalcopryite associated with the galena.

It is a curious circumstance (proved, however, by more than one prospecting pit) that the bedrock on top of some of the hills is covered to a depth of 10 to 20 ft. with earth carrying loose and rounded boulders. On the slopes of some of the hills the bedrock is much nearer the surface than on the summits, but this may be due to greater erosion below the summits. This seems to be more especially the case where diabase and gabbro are the rocks in place. The

Keewatin hills do not appear to carry so heavy a cover of earth, etc.

After the ice on lake Temiskaming has become thick enough for travel and when the winter road from Haileybury is open for traffic, shipments from this new district may probably attract attention to it.

FUEL, TIMBER AND POWER

The district is fairly, although not abundantly, timbered and there is no lack of water. The winter is severe, requiring snug camps and plenty of wholesome provisions. Those who own claims and wish to develop them are strongly advised to build camps early and gather and pile wood for fuel and timber for mine purposes. The forest fires that swept through that region during the last summer did little damage to mine timber, but they caused much of it to fall. The timber is scorched and blackened, but the heart is still sound and the "lumber jacks" are hard at work, securing all they can get. In the case of fallen timber it seems to be "first come, first served." The result will be that in addition to the standing pine which the lumbermen are entitled to, they will take everything they can find. Next spring when camps are to be built and timber must be provided for development work, etc., some of the claims will have difficulties.

Of interest in connection with the further development of the district is the power plant on the Montreal river that proposes to pipe air to the mines around Cobalt. A great deal of money has already been expended on this undertaking and it is now said to be so far along as to warrant the expectation that the power will be available next summer. This new district is much nearer the power plant than is Cobalt and it may be able to secure power at a lower cost. If, however, this should not be the case there is a fine waterpower at "The Notch," near the mouth of the river, that could be utilized either for compressed air or for electric power. It is not more than 7 miles from the Notch to the heart of this district. Cheap power would greatly aid the development of this district. It would solve the question of water supply, by no means an unimportant one even in this land of lakes and rivers.

PROSPECTING

A large amount of work, especially trenching, can be carried on during the winter to better advantage than during the summer or fall. There is much less trouble

*Mining engineer, Birmingham, Ala.

from water and the ground being frozen, stands better. Trenching is characteristic of the Ontario silver regions and is necessary. While the general course of the veins may be known—in this district they bear northeast-southwest—there are other veins that run north-south and east-west. Each promising "draw," or depression, must be prospected by trenching and pitting and a well opened property looks like a freshly plowed field. A prospector in the Cobalt district put the matter well when he said that a bucket of water and a broom were as necessary as a pick and shovel. Not every crack is worth investigating, but, as a rule, every fissure that shows calcite, especially if Cobalt bloom is present, should be opened. Cobalt bloom (hydrous arsenate of cobalt) is usually associated with silver. It is to be regarded as a more positive indica-

the chief ore of this new district yet argentite is also present and some cobaltite, smaltite and niccolite are also silver-bearing.

This district is likely to come into prominence as a silver producer within the next 12 months. It is easily accessible, has favorable geological conditions and is a promising field.

The Washoe Smelter

The accompanying illustration of the Washoe smelter of the Anaconda Copper Mining Company shows all the departments of this enormous plant. Its chief supply of ore is obtained from the mines of the Amalgamated and subsidiary companies at Butte, Mont. The plant has a

The method of sinking employed was as follows: Six-foot timber sets were used, bearers or foundation girders being placed under each end piece and every alternate divider or vertical at about 100-ft. intervals. When the running ground was encountered 3 ft. sets were substituted. The faults, being nearly vertical, caused the rock to scale off continually. Finally a set of three bearers, 9 in. wide under the end pieces and 7 in. wide under the dividers by 27 to 36 in. deep, all firmly wedged into hitches cut from 1 to 4 ft. deep were placed to take the weight of the timbers. A floor was built upon these, leaving only the hoisting compartment open; the shaft was then lined to near the top of the caving ground, and waste, hoisted from below, was filled in behind the lagging.

WASHOE SMELTER, ANACONDA COPPER MINING COMPANY, ANACONDA, MONT.

tion than annabergite (hydrous arsenate of nickel) and wherever it is found in association with calcite considerable work is warranted. The mud seams that lie next to the wall are also of importance in this connection. These are generally of a red-brown color and have a pasty consistency; they may go down to a considerable depth. Some of them carry considerable native silver and they are by no means to be neglected. On panning this mud many small fragments of wall rock and calcite are found with grains of yellowish sand and black iron sand. The silver in this material is nearly always badly corroded; the little nuggets are eaten into and the plates are honeycombed. These mud seams sometimes afford beautiful specimens of Cobalt bloom and nickel bloom, the former in radiating clusters of needle-like crystals of an exquisite rose color. While native silver is

capacity of 10,000 tons of ore per day, and is the largest of its kind in the world. The illustration tells its own story.

Shaft Sinking Through Faulted Ground

C. B. Saner (*Journ., Chem., Met. and Min. Soc. of South Africa*) gives an account of how, at the Turf mines, sinking through heavy cross-faulted ground was accomplished. The shaft in question is a seven-compartment one, and the bad ground was encountered at about 2650 ft. According to a custom of the region the shaft was sunk with the long axis across the formation. This gives greater strength, the long ledges of rock being exposed on the strike, as in the case when the long axis is parallel with the strike of the formation.

When more bad ground was encountered farther down three diagonal supports were placed below and supporting the bearers; two of these were 36 in. deep, the other only 24 in. They were set in cement in hitches cut about 5 ft. in the wall of the shaft and were, of course, made to fit as nicely as possible for they had to clear the steel guides. These cross-braces served to hold the worst part of the wall. Sets at 3-ft. centers, close lagged with 3-in. material, and with extra blocking behind every divider, firmly wedged in place and afterward filled in behind with waste, were continued until good, solid walls were again met.

This sinking was slow, for the timber had to be kept within 6 ft. of the bottom of the shaft, thus necessitating careful blasting and working of the bottom. The result justified the trouble taken and the work, now completed, is in good shape.

Pyrites in 1908

By J. J. RUTLEDGE*

Conditions in the pyrite trade during the year 1908 were very much better than for the preceding year, and indeed much better than the outlook at the beginning of 1908 seemed to promise. Shipments were much larger than during the preceding year, and, as the market will only absorb a certain amount of pyrite, prices were cut to a considerable extent in order to get the business. Moreover, as the demand was not materially greater than during 1907, prices could not be maintained, and considerable cheap material was sold. It is hardly probable that 1909 will experience as low prices as the past year, for in 1908 several of the mines in Canada and the United States sold their product very nearly at the cost of production.

Generally the acid manufacturers make contracts for three or more years in advance, in order to insure them a constant supply for their furnaces; this fact has helped to tide over what would otherwise have been a bad year, for some of the producers. Unfortunately several of the largest contracts expire at the beginning of 1909, and, owing to present market conditions, as well as the recent money panic, the acid makers are not in a hurry to make new contracts, feeling sure that they will be easily able to secure sufficient supplies for their use no matter what new developments may appear in the market.

THE TENNESSEE PLANT

The close of the year finds the pyrite miners and acid manufacturers anxiously watching the developments at the new acid plant of the Tennessee Copper Company, at Ducktown, Tenn. The 1000-ton acid plant, recently put in operation at this plant, has caused considerable apprehension. The fact that the Ducktown Company has also under way an acid plant equal in capacity to that of the Tennessee Copper Company, has caused the acid men to delay in making new contracts for pyrites, thinking that they may ultimately be able to secure acid from the Tennessee company at such a price that they will not be under the necessity of making their own acid.

The formation of a new fertilizer combination to take over the plants which were not taken over by the two preceding combinations, to utilize the acid made by the Tennessee company, does not seem to progress rapidly, doubtless owing to the fact that the terms offered some of the largest independent producers for their plants, does not seem attractive to them. While ultimately, to be sure, the large production of acid by the copper company, will greatly cheapen acid, and cor-

respondingly demoralize the market for acid, still it is not thought that this will occur for some time, as the company would have little to gain by such a course. The cheapening of acid will have a stimulating effect on all industries which employ chemicals. Especially will it benefit the farmer, for he will ultimately secure cheaper fertilizers. The fact that such States as Wisconsin, Illinois and Ohio are now commencing to use fertilizers, is of great importance. The field for the fertilizer manufacturer of the future is the Middle West, and some manufacturers are already planning to erect plants at such points as St. Louis.

Another probable effect of the reduction in the cost of acid will be that many small manufacturers of fertilizers, located in the farming districts, will purchase the cheap acid from the large acid makers and mix their own fertilizers. This has heretofore been done in a small way, and the advent of cheaper acid will doubtless result in more of this sort of manufacture.

The zinc smelters in the Middle West, who make acid as a by-product, and who have usually heretofore disposed of their surplus in the Southern States, will now, of course, be compelled to dispose of their product elsewhere, since the copper company will supply this market. The erection of fertilizer plants at such points as St. Louis, will operate to the advantage of the zinc smelters.

While the Tennessee company will doubtless control the market for acid in the Southern States, and may even displace considerable Spanish pyrite at Gulf and Atlantic points, freight rates will not permit of its shipment north of the Ohio river. It is cheaper to transport pyrite than acid, and this fact will limit the markets of the new acid plant.

It is not certain that the present acid makers would be willing to dismantle their plants and depend wholly upon the new works for their supply of acid, since such a course would place them wholly at the mercy of the large acid producer.

EFFECT ON PYRITE MINERS

It is a singular fact that those pyrite mines which have always held securely a certain local market adjacent to themselves, seem more strongly entrenched than ever, for only in one or two instances does the new order of things in the acid business affect them.

The recent developments in pyrite mines are in Canada and Georgia, the former, as in past years supplying a high-grade material, shipped mostly as lump, while the latter is producing almost altogether fine mineral. At every mine methods of mining and concentration are being constantly improved, and the cost of producing gradually lowered. Breaking is gradually coming to be done by mechanical means instead of by hand, the Blake type of crusher being used at some

mines, while at least one new plant is using a Gyratory crusher.

The outlook for 1909 is not very encouraging, since producers of acid are not inclined to make forward purchases, but it is thought that the market will ultimately work out satisfactorily.

Bogus Mining Experts

Employment by the U. S. Geological Survey, for even a short time or in any capacity, appears to have a commercial value that is rated high, says that organization in a recent press bulletin. Even the cooks and teamsters of the field parties refer proudly to their connection with the Survey and reap the reward of popular credit that attaches to their public service.

The advertisement of such connection after it ceases, however, has sometimes been the source of trouble or embarrassment to the Survey, especially where it is used for the furtherance of doubtful mining schemes, and the Survey desires to give emphasis and wide publicity to the fact, now fairly well known, that no member of its scientific corps is allowed to do private professional work in the United States during the period of his employment. The public is warned to look carefully into the statements and the standing of any practicing mining engineer who advertises present connection with the Survey.

The fact that the staff of the Geological Survey is not composed exclusively of geologists is too often overlooked. Of the 1200 or more persons connected with it in 1908, not more than 10 per cent. are geologists, and not more than 1 per cent. are engaged in work whose character implies ability to determine the merits of a mining prospect of enterprise.

Flotation Process Litigation

In the case of the British Ore Concentration Syndicate, Ltd., and Alexander Stanley Elmore vs. The Mineral Separation Company, Ltd., Justice Neville, of the High Court of Chancery, pronounced judgment to the effect that the Mineral Separation Ltd., was not infringing the patents of the plaintiff. The latter appealed from this decision. The Lord Justices of the Court of Appeals rendered judgment Dec. 2, 1908, to the effect that the Mineral Separation, Ltd., was not infringing the patents of 1898, but was infringing the patents of 1891. The case will now probably go to the House of Lords, which is the final court of appeals.

It is not always an advantage to connect several mines, since the farther air travels through mine workings the more it becomes vitiated.

*Mining engineer, 213 Courtland street, Baltimore, Md.

The London Silver Market in 1908

The following concise review of the market in London,* where most of the silver produced in the world is handled, is made by Messrs. Pixley & Abell, of that city.

THE COURSE OF PRICES

The heavy fall in silver, which took place toward the close of 1907, was followed during the opening months of this year by a reaction, due chiefly to large purchases for the Indian bazaars, and during January the quotation rose to 27d., the highest of the year, an advance of 2½d. from the closing price of 1907. This steadiness continued until the beginning of April when weakness again set in, and from that time the tendency of the market, with the exception of a temporary advance in June, was downward until December 2, when 22d., the lowest quotation of the year, was touched. From this point the market steadily improved until the end of the year, when the closing quotations were 23 3/16d. for spot and 23 3/8d. for forward silver. Important purchases for China and some buying for India, where the position has of late become more satisfactory, account for this sharp advance during the last few weeks. The average price for the whole year is 23 13/32d. per ounce.

SHIPMENTS TO INDIA

Shipments to the Indian bazaars were throughout the year on an unusually large scale. The net imports, chiefly from this country, into India probably amounted to 70,000,000 oz. against 44,500,000 in 1907, and 32,750,000 in 1906. This demand may to a great extent be attributed to a desire on the part of the natives, attracted by the low prices, to convert their hoards of rupees into bar silver, and this action has doubtless been partially responsible for the increase of rupees in the Indian treasury. There were an unusual number of marriages during the early part of 1908, as in July commenced a period which will extend until October, 1909, and which is considered by the Hindoos to be unpropitious for matrimony, and this fact doubtless stimulated purchases during the earlier months. The cheapness of silver has also probably conduced to the purchase of this metal instead of gold, of which only about £3,100,000 in bars has been sent to India in 1908, against £5,700,000 in 1907, the difference representing in silver some 25,000,000 ounces.

Indian speculators have during the last six months operated largely both in London market and Bombay. Though these speculative accounts have not yet been liquidated the immediate result has been to transfer large amounts of silver from London market to Bombay, where, in spite of some substantial purchases for

China, the stocks are still heavy, amounting, it is estimated, to nearly £400,000, while in addition there are £840,000 now in transit.

The Indian Government made no purchases during 1908. Its holdings of rupees have largely increased and amounted at the beginning of December, when the highest point was reached, to about 29 crores in the paper currency reserve and to 18½ crores in the gold standard reserve. Since then, owing to the opening of the export season, the paper currency reserve has fallen to just under 28 crores (£18,500,000), and the gold standard reserve to 18 crores (£12,000,000). At the commencement of the year the Government's holdings were 21 crores (£14,000,000) in the paper currency reserve and 6 crores (£4,000,000) in that of the gold standard. Under these conditions the prospects of further purchases during the coming year are rather remote. To coin 1 crore of rupees requires 3-437,500 fine oz. silver. As 15 rupees equal £1, a crore of rupees equals £666,666½.

CHINESE BUYING AND SELLING

Though China has at times been a seller, and has shipped about £220,000 in sycee to London for sale, yet she has, on the whole, been a considerable buyer. The low exchanges ruling in China have greatly stimulated the export trade, and adversely affected the import trade so that the banks have been forced to buy silver as cover for or as a hedge against their exchange operations. Part of these purchases have been shipped to China, but a large amount is still under the control of the China banks. Whether this will be re-sold or shipped to China remains to be seen. In addition to her purchases in London, China has bought fair amounts in Bombay and has as well received regular shipments amounting to about £1,000,000 from San Francisco. An important feature in the future will be the effect of the prohibition of the import of opium into China, should this result from the recent efforts to suppress the use of this drug. Unless the import of other commodities should greatly increase, it would seem probable that China will be a still more important buyer of silver than heretofore.

In Shanghai the stock of sycee is unusually heavy, amounting to about 19,000,000 taels, while in addition there are 10,000,000 Mexican dollars.

MINT BUYING

A convention was signed in November by the members of the Latin Union whereby it has been arranged to increase the circulation of subsidiary coins from 12 to 16 fr. per head of the population. This convention comes into force on April 1 next, and the increase is to be made at the rate of 60 centimes per head per annum. There are also provisions to allow Italy and Greece, where the cir-

culation is now below 60 centimes per head, to bring the circulation up to that amount. As a large part of the silver required will be provided by re-coining five-franc pieces, or coins of similar value, the amount of new silver required will be unimportant. Excepting 5000 kg. bought during December, the Paris Mint made no purchases by tender in 1908. Silver, however, was brought for French account during the earlier part of the year, and this presumably was required for colonial coinage. Switzerland has been a moderate buyer at times, while Portugal bought £250,000 in October.

In Germany a bill has passed the Reichstag for the purpose of increasing the silver currency of the country by 5 marks per head during the next five years. This is estimated to require about 1,250,000 kg. of silver; but so far, we understand no purchases have been made.

During November, the Mexican Government offered to buy 5000 kg. monthly for currency purposes.

EFFECT OF LOW PRICES

The low average price of silver, which has ruled during the last 15 months, has, no doubt, caused some diminution of production. Where ores are mined principally for copper, lead or other metals, and silver is but a by-product, low prices for silver can have had little effect, but many of the poorer mines, especially those which depend mainly on the production of silver, have certainly reduced their output. Against these reductions must be set the increased production from the Cobalt district of Canada, but it is probable that, when reliable figures are available, the world's production will show some decrease.

THE FUTURE

With silver at low level—almost down to that of 1902-3, when 21 1/16d. was the lowest quotation touched for spot silver—it becomes interesting to review the present situation and consider the prospects for the future. Though the Indian government is unlikely to be a buyer for some time to come, and though China has unusually large holdings of silver, the larger offtake by the Indian bazaars and the possible falling off in production will, in all probability, suffice to prevent any further material decline. Much, however, will depend upon whether China resells any of the silver under her control in London, or whether fresh purchases are made on her behalf.

An alloy of iron, cerium and lanthanum will give off luminous sparks when struck with steel, the sparks being capable of igniting illuminating gas. The behavior of this alloy varies with the percentage of iron, the maximum sparking effect being observed when the iron is about 50 per cent. The sparking phenomenon is brilliant.

Standard Oil Companies

The following list of companies controlled by the Standard Oil Company of New Jersey, the most complete list of the kind ever made available for public inspection, was compiled by the New York *Sun* from the exhibits made in the present proceedings of the Government against the company:

I. COMPANIES WHOSE STOCK IS OWNED DIRECTLY BY THE STANDARD OIL COMPANY.

Name.	Total Capital Stock.	Per Cent. Owned by Standard.
Anglo-American Oil Co., Ltd.	\$5,000,000	100
Atlantic Refining Co.	5,000,000	100
Bedford Petroleum Co.	350,000	99.3
Bethlehem Petroleum Co.	300,000	99.9
Buckeye Pipe Line Co.	10,000,000	100
Carter Oil Co.	2,000,000	100
Chesbrough Mfg. Co.	500,000	55.5
Continental Oil Co.	300,000	100
Colonial Oil Co.	250,000	99.7
Crescent Pipe Line Co.	3,000,000	100
Clarksburg Light & Heat Co.	100,000	51
Deutsch - Amerikanische Petroleum Gesellschaft	2,250,000	100
Deutsch - Amerikanische Petroleum Gesellschaft (share warrants)	5,250,000	99.9

Grand total.	\$328,301,495	

Of course to a certain extent the capital stock of the Standard Oil Company of New Jersey represents a repetition of some of the recorded capital stock of certain of the subsidiary companies.

Rhodesian Gold

Completed returns from the Rhodesian Chamber of Mines value the gold production in November at \$957,118; a small decrease from October, and a considerable gain over November, 1907. For the 11 months ended Nov. 30, the total value of the production was \$9,677,370 in 1907, and \$11,235,631 in 1908; an increase of \$1,558,255, or 16.1 per cent.

Sampling Devices

In sampling shafts and winzes two devices, described by H. E. Hooper in *Bull.* 49 of the Institution of Mining and Metallurgy, are useful. One is a chair with an adjustable arm projecting from behind so that by means of this arm and a thumb-screw the sampler can secure himself at any point in the winze or shaft. The projections in front serve as the forward braces. The chair is swung by four short ropes from the windlass cable.

The bag for catching samples, shown in an accompanying illustration, is semi-circular in shape. The top consists of a semi-circular loop of $\frac{3}{4}$ -in. round iron to which a canvas bag is sewed so that it falls vertically from the straight edge of the hoop. The semi-circular side is convenient in catching the sample from

ordinary depressions, the straight side for regular faces, and the corners for acute depressions. When used in conjunction with the chair the bag is attached by a cord from the center of the circular side to the rope above the sampler's head so that when the back of the bag rests against the sampler's knees the bag is horizontal.

In Australia considerable State aid is given to mining. In Western Australia there are 29 State stamp mills and 21 State cyanide plants. Prior to Jan. 1, 1908, 505,286 tons of gold ore was treated, and gold amounting to £2,036,156 was extracted in the stamp mills and £277,166 in the cyanide plants, while tin, valued at £52,015 was obtained from the 31,166 tons of tin ore treated in State batteries. Except for expenditures on additions and improvements, these State batteries were self-supporting.

The Zinc Corporation, Ltd.

This company was organized several years ago to deal with the tailings at Broken Hill, of which it purchased several million tons. H. C. Hoover was largely instrumental in organizing the company and has been its technical director. It was the intention to employ the Potter flotation process, but this proved a failure and the company passed through a series of experimental vicissitudes which carried its fortunes to a low ebb. Under the orders of Mr. Hoover the Elmore vacuum process was finally installed, and from the beginning of its application in 1908 the indications have pointed to success. At the end of 1908 it could be pronounced that both the process and the Zinc Corporation are successes. This is a great, and well-deserved triumph, for Mr. Hoover. In this connection the statement made by him at the annual meeting of the company, last July, is of peculiar interest. In substance it was as follows:

The ore at Broken Hill contains lead, zinc and silver. The mining companies there crush this ore to the fineness of sand and extract from it, by water concentration, about 60 to 70 per cent. of the lead and silver contents. The residues from this treatment, which are sent to the dumps, contain, therefore, practically the whole of the zinc and between 30 and 40 per cent. of the original lead and silver in the ore. We have already bought and paid for a million tons of these residue dumps, and we have the right to buy some millions of tons more. The residues we are treating at the present time are those from the Block 10 mine, and they average about 20 per cent. of zinc, about 8 oz. of silver, and 5 or 6 per cent. of lead. We take the residues from these old dumps by our own railway and dump them into large bins which we have prepared underneath the track at our works. From here the material is carried by a belt-conveyer to bins at the top of the mill. Thence they pass to Huntington mills and grinding pans. After this regrinding, the material passes to agitators, where it is mixed with oil and sulphuric acid, and is drawn from the agitators through the Elmore vacuum machines which deliver a mixed zinc, lead, and silver concentrate.

The second stage of the treatment is the separation of the lead from the zinc in this mixed concentrate, making one in which zinc predominates and one in which lead is the principal content. The zinc smelters will pay only for lead in excess of 8 per cent., and then only half the value of the lead. Likewise, they will pay only 1s. 3d. an ounce for the silver over 5 oz. a ton, and then pay for the zinc content at the average price of zinc over the year of purchase, less the cost of shipment to Europe, smelting charges, loss in recovery, and their profit on smelting. Nor will the lead smelter pay for zinc in the lead concentrate.

fact, he penalizes us if we have over 12 per cent. zinc in our lead.

The average contents of the mixed concentrate is about 43 per cent. zinc, 12 per cent. lead, and 16 oz. silver. From this we are now obtaining lead concentrates at the rate of 230 tons per month, and by doing so we have increased the contents of the zinc concentrates from 43 per cent. to 47 per cent. zinc. On our present output, if we sold the mixed concentrate as it stands, we should realize about £3500 less than we do realize by first separating a portion of the lead. On the basis of our last week's output we are earning a net sum of £7000 per month above all expenses, out of which about £3000 should be set aside for cost of tailings worked up, or a net amount of about £4000 per month, or £48,000 per annum profit. I am in this taking metals at the bedrock prices I have mentioned (zinc, £19¹/₄ and lead £12¹/₄) and taking working expenses at their average for June.

This profit is, I believe, capable of very important increase from many directions, and it is the directions from which these increases may be anticipated that I wish to make clear. First, the working expenses are always high at the initial stages of a new plant. Although our plant is absolutely mechanical, and no human hands touch the material from the beginning to the end, it takes months to train men and organize them to the best advantage. In this business men have had to be trained from the ground up, as this is entirely a new business in which no men of experience can be obtained. Moreover, we have been buying water, and we shall soon have our own supply for at least part of the year. Our expenses at the start were about 14s. per ton, and for the month of June were reduced to 12s. 3d. per ton. I believe it will be ultimately decreased to 8s. per ton, which would give an additional profit of over £2500 per month. Second, the mill is treating about 13,000 tons per month. I believe that by gradually strengthening the weaker links of the plant this can be increased by 1000 or 2000 tons a month. This would mean an increase in working profit by £500 to £1000 per month. Third, we are obtaining an extraction of over 88 per cent. of the original zinc contents of the residues. This shows an increase from about 72 per cent. the first month. We have obtained in systematic experimental work as high as 92 per cent. extraction of the zinc, so that we may make a minor improvement here, although we have not much room for improvement over present results on this line. Still, an additional 4 per cent. recovery would augment our profits by £500 per month. Fourth, the improvement in treatment of the mixed lead and zinc concentrate is one of the most important matters with which we have to deal, and one which very important possibilities lie in. The expectations of Mr. Hoover as to

increased profits have already been realized to an important extent.]

The lead extraction from the original residues at present average about 70 per cent. in the Elmore concentrates; but we get out of the mixed concentrates only a part of the lead in them, equal to an actual extraction as final salable lead of only 17 per cent. of the lead in the original material. In experimental work we averaged a recovery of 40 per cent. of the original lead, instead of 17 per cent., as above. We hope eventually to duplicate this in regular operation of the plant. If we do so, the increased profit from the extra lead and the further increased purity of the zinc would, on present tonnage, and at the metal prices I have given, amount to between £2500 and £3000 per month. We have, therefore, a possible increase of the present profit from reduction of expenses of £2500 per month, from increased zinc extraction £500, from increased tonnage £500, and from increased lead extraction £2500—or a total of £6000 per month, or £70,000 per annum, and this without increased price of metals. To do this, or something approaching it, we shall need to lay out £7000 to £8000. To recapitulate, at the present moment we are earning a profit above the cost of the material we treat, and on present low prices of metals, of about £48,000 a year. If we succeed in these technical improvements we shall raise it to over £100,000 per annum. I cannot guarantee that we shall accomplish all this. We have had such results for short periods, and every week since we started has shown some improvement. One thing I can say, and that is, we will accomplish part of it.

A New Vertical Duplex Pump

The Blake and Knowles Steam Pump Works, of New York City, has recently perfected a vertical duplex pump of new design, and small in size, for boiler feed or general work under high pressures. The pump cylinders are of the piston pattern, lined with brass, and the steam cylinders of the company's regular duplex design. The cast-iron cradle or center piece, which ties the steam and water ends together, is extremely rigid. The cylinders are fitted with brackets for bolting the pump to a bulkhead or wall. The pump is suitable for a working pressure as high as 200 lb. per square inch.

When dynamite burns, the chief danger, other than from its liability to explode, is from breathing NO formed by the combustion and which oxidizes in the presence of oxygen to NO₂, the red fumes. Both these gases are very irritating to the throat and air passages of the lungs. Acute bronchitis frequently results from breathing them.

Colliery Notes

When shots are fired by electricity, the button of the battery should not be pressed until a high speed has been obtained in the armature.

In firing shots electrically, many precautions must be observed. The cable, or firing line, should not be allowed to "kink;" it should either be "reeled" and "unreeled," or otherwise carefully coiled. If a "kink" does occur in the firing line, it should not be given a short pull to straighten it out. It should be twisted carefully back again into its straight line; the operator should always remember that much trouble is caused by the wire becoming broken inside the insulation; this is what usually happens when "kinks" are pulled vigorously.

In analyzing the common type of direct-current motor as used today, it is safe to say that the "starter" is a most important part of the controlling apparatus. A good starter should possess the following points: (1) A dead handle or lever so constructed that no current passes through the handle proper. (2) No current should pass through hinged or movable joints. (3) Completely inclosed and fireproof resistances. (4) A frame which cannot become "alive" due to burned out coils. (5) Easy replacement of coils. (6) No soldered connection.

In connecting up the wires, when all shots are fired by electricity, the extremity of the wires should be carefully cleaned by scraping them bright with a knife, laying the extremities across each other, in scissor fashion, and then twisting the free ends over each other a few times. The jointing is very important, for if the connection is made with dirty ends, the external resistance is so increased as to materially affect the firing capacity of the exploding machine. It is also a fact that a clumsily formed joint may be so ineffective as to cause a misfire.

Two English miners have designed a simple invention, with the object of providing greater safety for those riding in the shaft. The scheme is to have two ropes attached to each cage; one of these cables will be the working rope, while alongside of this there will be another rope, slightly longer. If the working rope were to stretch, which would be the case when it approaches the breaking point, then this additional rope would come into operation and take its share of the weight and thus prevent the accident. In case the working rope should break, then the auxiliary rope takes the full weight of the cage and its load. The invention is effective and inexpensive.

Many dangers always attend shaft sinking, and because of the hazardous nature of the work, every possible safety precau-

tion should be observed. In carrying on sinking operations, the foreman should see that all loose stones or suspicious sides are properly timbered or drawn down. This is most important when a shaft is crossing a disturbance, for shafts have been known to collapse after a sharp-angled fault has been crossed. The shots should be fired by electricity, thus minimizing the risk of miss-shots; also they should be fired simultaneously in order to avoid the danger of returning for new connections when firing singly. When approaching a coal seam, it is essential to keep a sharp lookout for firedamp blowers. The engine driver should at all times have full view of the pit.

In the arrangement of "winding signals" from different levels in a shaft, the old system of having a galvanized wire leading from a bell in the engine house and being worked at the different levels by levers, has been almost entirely replaced by the adoption of electrical signaling. In this latter system, a battery of the Leclanche type is suitable, being simple in construction and needing but slight attention. The single-stroke bell is much superior to the trembler bell. The signal wires leading from the bell in the engine house down the shaft, should be properly insulated and be carried down the shaft in grooved boarding; this method is more expensive, but will be found cheaper in the end. The diameter of the insulated wire should be slightly larger than the groove, so that the former can be gently tapped into the groove and covered over by a light boarding. When this plan is followed, there will be no danger of leakage of the current.

It is a matter of great importance to the safety of our miners, that every precaution be exercised when entries or chambers approach old workings. Our mining laws in many States neglect to prescribe rules tending to create greater safety under such circumstances. When an entry is approaching a place likely to contain a dangerous accumulation of water, the heading should not at any point within 100 ft. of that place, exceed 8 ft. in width; it is advisable to further require that at least one bore-hole in the center of the heading should be at least 15 ft. in advance; several flank bore-holes should be drilled on each side. The following signs will sometimes indicate that a heading is approaching a dangerous place: A large number of breaks or cracks are found in the roof, floor and coal; the coal is often discolored to a brown or yellowish hue; an absence of gas in the coal; oozing of water from the strata; lights burn dull, due to the amount of carbonic-acid gas given off from the breaks in the strata.

An investigation of accident statistics, as compiled by the mining departments of several European countries, shows that in recent years, since all explosives have

been made to conform to set standards of safety, accidents due to blown-out shots have decreased more than one-half. The question now confronting European coal-mine managers, is concerned with the advisability of using safety lamps exclusively in all underground workings. There are two arguments advanced against the adoption of safety lights: First, the men demand an increase of wages when safety lamps are introduced, and the mine owners raise objection on the score of economy; second, it is contended that the safety lamp does not give so good a light as the naked flame, and that the former, because of its inferior illumination is dangerous to workers because of their inability to see the roof plainly, and thus avoid falls of top and sides. The first objection to the abolition of naked lights is prompted on the part of both miner and operator by their desire for material gain. As to the second argument, the reports of a number of inspectors in districts where safety lamps have been introduced, do not show that the introduction of these lights has increased the number of accidents; on the other hand, the report of one of the inspectors shows that of 184 explosions of firedamp or coal dust, no fewer than 160, or 87 per cent. were attributed to naked lights.

Because coal-mine accidents have left so many widows and children without support, it is being widely suggested that the different States levy a tax on all the coal produced so as to create a relief fund to aid these unfortunates. Among the many schemes proposed, the chief inspector of Pennsylvania has suggested that the State levy a tax of $\frac{3}{4}$ ¢ per ton on all bituminous coal sent to market or used in the manufacture of coke, and a tax of $\frac{1}{2}$ ¢ on each ton of anthracite coal sent to market. Anticipating a fair average increase in the production of coal in Pennsylvania during the coming years, this plan would insure the State an annual income of about \$1,500,000. Statistics show that on an average, coal-mine accidents in Pennsylvania leave 574 widows and 1316 orphans each year. The Pennsylvania inspector's proposal would insure each widow \$100 to defray funeral expenses and a weekly benefit of \$2.88 during widowhood; each child under 14 years of age would receive a weekly benefit of \$1.92. In addition to furnishing this relief for widows and orphans, approximately \$100,000 per annum would be distributed for the succor of disabled miners. The additional cost of production entailed by the adoption of this system would eventually have to be paid by the consumer. The person who consumes ten tons of coal in a year would have an additional expense of about $\frac{7}{8}$ ¢; the person who uses 40 tons of coal a year would have an additional expense of 30 cents.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Prop. and Treas., ROBERT McKEAN, Secy.

London Office: 6 Booverie Street, London, E. C. 4, Eng.

CABLE ADDRESS "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 53 marks; or 40 francs. Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 are printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for December, 1908, was 42,500 copies.

January 2..... 10,000

January 9..... 14,000

January 16..... 10,000

January 23..... 10,000

None sent free regularly to back numbers.

The U. S. Geological Survey in 1908

The report of work done by the U. S. Geological Survey in 1908, published nearly in full elsewhere in this issue, shows once more the extent to which this organization has abandoned its proper field—the field in which it won its spurs—in order to disport itself in paddocks wherein it has no real business to be. The science of geology and the study of ore deposits are relegated to the background while attention is concentrated upon statistics, water resources, development of water power, mine explosions and rescue work, the testing of building material, etc. Its own statement is good evidence of the commercial spirit that now pervades the Geological Survey.

One reason for this is not hard to find. The results of study of science are generally non-spectacular. To but few is it given to surprise a secret of nature, to discover a new element or disclose a new scientific principle. The work of the multitude of scientists is to add laboriously, brick by brick, to the great structure, generally without any identifying mark that lives. On the other hand, investigation of economic subjects may win immediate applause from the public. Bulletins can be issued to the press, which to more or less extent gives them circulation. The organization is kept constantly before the public eye and so it becomes easier to secure appropriations, which is what the organization wants.

Director Smith means well, but he has not yet been able to shake off the malign influence under which the Survey suffers. At present, his organization has gone mad over what it considers to be economics. The conservation of resources has been hailed as a new idea that promises an expansion of the last appropriation of 134 millions of dollars. Learned essays are written about waste that may be prevented, with little or no attention to the economy of doing so. (Such a sober consideration would seldom lead to the spectacular result that is desired in order to gratify the imagination of the public).

What the miners really want is advice and information respecting the discovery of ore. If the Geological Survey will aid in that, the engineering profession will take care of the rest. But apparently this is not what the Survey is now most anxious to do. Let us point out to the Survey

that a Leadville report and the discovery of a scientific principle, like that of secondary enrichment, are of vastly more importance to the mining industry than all of the frothy information that has been communicated during recent years.

The European Zinc Convention

The European zinc convention, of which we reported the organization in our issue of Jan. 9, is the consummation of plans that have been under consideration for a year or more. We are unable yet to give the full details of the program, but what we have already reported is sufficient to show that the plan and scope have been devised with unusual ingenuity, in order to avoid the pitfalls that have caused disaster to previous conventions. The fundamental purpose of the new convention is to regulate the price for spelter, which means, of course, to keep the price at a high figure. Such a purpose is unholy and is to be condemned. We suffer in the United States from evils arising from the trusts, but we have not gone so far as the European countries, which permit cartels and conventions that would be illegal here.

The European zinc convention is organized at an opportune time, inasmuch as no immediate danger of importation of spelter from America is to be anticipated there. The cost of producing spelter in this country has risen so much because of the necessity to mine a very low grade of ore in order to supply our domestic consumption that the chances are that our smelters will not be in a position to export spelter for some years to come. Yet, we are disposed to think that the present tendency toward a rising price for spelter will not be permanent. Sooner or later, new discoveries of zinc ore will be made that will restore us to our old position of economic production. Moreover, it is possible that zinc smelting may some day be inaugurated on the Atlantic coast, importing ore from Mexico, South America, Australia, and elsewhere. Such a scheme would be by no means impracticable, and if the European convention maintains a high price for spelter, American financiers may be attracted to go into it.

THE INDEX to volume 86, covering the second half of 1908, is mailed to all subscribers with this issue of the JOURNAL.

Some Reflections on Coal Mining

The coal industry in the United States has grown with amazing rapidity. Since 1899 when this country wrested the supremacy from the United Kingdom, its coal output has increased so that at present we are producing upward of 200,000,000 tons more each year than the United Kingdom, our nearest competitor. However, an examination of the statistics of coal mining in this country shows that in spite of our successful growth, we have no reason to feel any great elation. In 1908 we produced more than 479,000,000 tons of coal, of which 80,000,000 were anthracite. Each ton of anthracite coal had a value of \$2.30, while each ton of bituminous coal was valued at \$1.15. Against these values the British coal operators can show that every ton they produce brings them \$2.16 at the mine, so that after all is considered, we in the United States cannot flatter ourselves on showing as great a profit per ton mined as our British cousins. Safety is also an important consideration, and when we place a money value on each life lost, it seems that we have small reason for rejoicing at our monster strides in mining coal.

Future Copper Resources

Fears are frequently expressed that the world's resources of copper are not going to be sufficient for the further expansion of the electrical age that is anticipated, and that for this reason higher prices for copper are to be looked for permanently. Good copper mines are indeed hard to find, but among the many worthless properties developed, some good ones are found nearly every year, and the experience up to date shows that these have been sufficient to maintain the required production at an average price not very different from what copper fetches at present. The resources of the world still being so far from measured why should not this condition be expected to continue? We are now beginning to realize large amounts of copper from the porphyry ore of Bingham and Ely, which only a few years ago were not thought of as possible sources of production. In 1908 an immense new deposit of this kind of ore was blocked out in the Miami

mine, near Globe, Ariz., which was the most important development of the year in America. This mine showed nothing but iron stains on the surface. The experience at Mt. Morgan in Queensland, and at Ely, Nev., and Globe, teaches that certain occurrences making no surface showing of attraction to the prospector of old may be underlain by immense deposits of this kind of copper ore. This is an important geological discovery, leading to the belief that there are important copper resources, hidden from the eye, which may be found by the application of modern science.

The British Iron Trade

While full returns are not yet available, the signs of depression in the British iron trade in 1908 are not wanting. The return made by the Scottish Association—usually regarded as a close guide to the general production of iron—shows a reduction of more than 12 per cent. in the make of iron, while the stocks on hand increased by 90,000 tons; the actual sales for consumption having decreased by nearly 20 per cent. This indicates a nearly parallel reduction throughout the United Kingdom. It is true that this decrease is much less, both actually and proportionally, than that in our own iron production; but fluctuations in the British iron trade are never so sharp nor so quick as in our own, and a loss of 10 or 15 per cent. is a very serious change.

Another indication is found in the export trade, which last year was less than in 1907 by nearly 11 per cent. The British exports form a larger proportion of the total trade than in this country, and such a loss implies an important reduction in activity. Moreover the loss was especially marked in finished materials, which constitute the more important and profitable part of the trade.

Prices of crude iron are also low. The latest advices show Middleton pig selling below \$12 per ton, and Scotch hematite, corresponding to our bessemer pig, under \$14. Tin-plate bars are quoted about \$21, with billets at a corresponding price. Moreover light demand and small sales are reported in all the market. Evidently the British iron masters do not open the year in much better condition than our own.

Recent Colliery Explosions

The explosions at the Lick Branch mine, Ennis, W. Va., Dec. 20 and Jan. 12, whereby 51 and 65 men were killed, and at the Leiter mine, Ziegler, Ill., Jan. 10, whereby 25 men were killed, occurring at this noteworthy period of earth disturbance, direct attention once more to the frequent close correspondence between these phenomena. Perhaps the most singular phase is that the correspondence is not local, but often occurs in widely distant parts of the globe. The earthquake in Italy was preceded by seismic disturbances in Montana, beginning Dec. 21 and continuing to Dec. 27. On Dec. 23 there were gas explosions in mines in Colorado. In November last the Marianna explosion was preceded by a few hours only by severe earthquake shocks in Boston. The Maypole disaster in England, Aug. 18, was likewise preceded by a few hours only by severe earthquake shocks at Eureka, Cal. It will be acknowledged by any candid mind that while a dangerous condition may exist in mines following seismic disturbances, local or otherwise, a mine explosion does not necessarily follow, since the ignition of the gas is necessary to produce an explosion. Also the ignition of gas in well regulated mines does not in most cases result in a mine explosion. However, it is obvious that, if there be any real connection between seismic disturbances and release of gas, a time like the present is one that should cause operators to be particularly on guard.

FURTHER PROGRESS in the use of mine timber, chemically treated in order to prevent decay, is being made. An anthracite coal mining company of Pennsylvania was the first to introduce this practice. Its lead is being followed by the Miami Copper Company, of Globe, Ariz., and by two lead-mining companies of the Cœur d'Alene. It has been aptly pointed out that if it be economical to preserve railway ties, which are not only cheap in first cost, but also are cheap to replace, it will be far more economical to treat mine timber which is dear in first cost and also in the labor expense for renewal.

STATEMENTS AS to the amount of copper in stock in this country, that have been much discussed this week, are undoubtedly far in excess of the actual condition.

Comments on Questions Arising in Technical Practice and
Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Testing Placer Ground

A good deal has appeared in the columns of the JOURNAL and elsewhere lately, regarding the testing of placer ground for dredging purposes by hand or steam drills, and I have personally spent a good many thousand dollars in this same manner for people who were anxious to obtain such ground. These articles have covered the subject in an exhaustive way and have been most excellent, so far as they go, but it seems to me a few words more might be added which would tend to make dredging examinations far less costly affairs in the aggregate.

We all know that placer ground suitable for dredging purposes is one of the most difficult things in the world to find; it is almost as scarce as are hen's teeth. At the same time, there undoubtedly is much unexplored territory in the world today, which would pay to prospect for this purpose, provided there is a reasonable chance of finding it worth the effort and not an absolute waste of money. My own experience in this line has led me to offer a few suggestions to the mining fraternity, as well as to the intending investor.

EXPENSE OF DRILLING

To drill a piece of ground of any size, and at all thoroughly, is very apt to entail an expense of from \$5000 to \$10,000; and if such work is done in the tropics of South America, or in other foreign countries, it may amount to very much more than that. Often the ground is proved to be entirely unsuitable for dredging purposes, and this money is practically thrown away on a worthless proposition, with the result that the investor feels disgusted. Such properties are occasionally brought to the attention of capitalists by men who are themselves satisfied that the ground carries sufficient gold and is otherwise suitable for this purpose, before the area has been drilled at all. These men have usually arrived at their conclusions honestly, by panning the surface in a casual manner, or by actually seeing some natives or local miners sluicing out "stakes" upon various parts of the property. I do not mean that dredging ground is always presented in this way, because sometimes it has already been partly drilled, but in that case the owners themselves or someone else has had to take this gamble in the beginning. It then resolves itself into a question of whether they have done the

work correctly or not, which I do not wish to touch upon here.

I have seen properties in South America, which were known to contain placer gold tested in a most superficial manner by desultory panning of the surface. With this information alone a company has been formed and an expensive dredge installed to work the ground, with most shocking results to everyone concerned. Of course, the ground should have been properly drilled in the first place; but the owners argued that their panning results apparently warranted them in going ahead without such a heavy expense as thorough drilling entailed. I am not trying to defend this argument for a moment, but I do think there is a method which might have been followed and which would probably have shown that the ground was either entirely unfit for dredging, or that it would warrant the expense of drilling.

TESTING BY PITS

In most placer ground the water level is found several feet below the surface, and sometimes it is possible to sink pits to bedrock with the aid of buckets or small pumps to keep the water out. But even if it is not possible to sink all the way down, a trained and expert panman in this class of work, which a placer engineer should be, can flag the ground at suitable distances, and, by squaring up small pits at these points, pan the material for each foot in depth separately. By taking a sufficient number of pans from each foot and uniting the gold so found for weighing, he can obtain a surprisingly close approximation of what the ground is worth to the depth he is able to sink conveniently. His experience in other fields will often tell him what to expect below the water level, where he cannot get.

Of course, this method of making a preliminary examination is perfectly obvious to every engineer, but to many promoters and investors it is not, and they might be slow to think that a property, turned down by a man using this method had been given a fair chance. That primarily depends upon the man who does the work. Unless he is a trained engineer deductions of this sort may be well founded; for the average promoter or investor, who undertakes to do this himself, he is ever so honest, is not apt to be cold-blooded, exact, or methodical in his work, leaving aside altogether the question of experience and lifelong training.

The expense of such a preliminary examination is trifling as compared with that of drilling the ground, and it may only show that the ground should be drilled anyway. A large piece of dredging ground can stand this extra cost; and if it is unsuitable for the purpose, the heavy expense of an examination by any kind of a drill has been saved. The total equipment necessary is a small pair of scales, costing about \$15, some acid and mercury, test tubes, annealing cups, an alcohol lamp, and a pan, together with the necessary digging tools which can be obtained anywhere. The engineer does all the work himself, with perhaps one or two ordinary laborers as helpers.

New York, Dec. 17, 1908.

Alumina in Copper Blast Furnace Slags

In recent issues of the JOURNAL I have noted Charles F. Shelby's quotations of Carl Henrich's articles relating his experience in New Zealand at the Champion mines in May, 1886, also Harley E. Hooper's criticism of Mr. Henrich's results in the issue of Dec. 5 and Mr. Shelby's reply in the JOURNAL of Dec. 26, 1908.

When Mr. Henrich's articles appeared in the JOURNAL of July 17 and Aug. 28, 1886, I fastened to them as containing the only practical information on the subject "Is Alumina an Acid or a Base?" at which everyone was having a whack about that time. I have carefully kept them ever since. I afterward gained some first-hand information concerning this work, which may prove interesting now. My own connection with the matter was through samples of ore sent to the Mt. Lyell works for treatment and for advice, and also afterward from negotiations in regard to my taking up the work provided a new company could be formed.

In conversation with the only surviving director of the old company, who came to the Mt. Lyell works to see the ore sampled, I mentioned the existence of those articles. He was greatly surprised, and when I showed them to him he remarked: "Why, we only ran twice, about three or four days altogether, when the bank shut us up." This, with the following facts, shattered my faith in the articles in question.

The total amount of ore smelted was small; Mr. Hooper says the whole dump contained about 100 tons. Mr. Henrich's

report to the company starts off, "There have been smelted during the last run a total of 119,416 lb. copper ore—" about 60 tons. The furnace was a 30-ton round copper furnace built by Fraser & Chalmers, of Chicago.

With the ore samples sent, which, by the way, contained 4.51 per cent. alumina, there was a sample of the old slag and one of the old matte. The old slag sample, which showed pieces of free matte scattered through it, gave the following result: Silica, 30 per cent.; iron, 37.9; lime, 9.5; magnesia, 12.42; alumina, 5.67; and copper, 1.22 per cent. This confirms Mr. Hooper's analysis.

Mr. Hooper's statement that practically no lime was given is not quite correct. In his samples Nos. 1 to 4, 1.5 per cent. is the highest lime given, but in samples Nos. 5 to 9, the lowest is 5.1 per cent., and the highest 15 per cent., with an average of 9 per cent.

I think with Mr. Hooper that the deductions of Mr. Henrich in this particular case are based on insufficient and inaccurate data and are, therefore, misleading. Mr. Henrich's difficulties were great; his isolation complete so far as men and material were concerned; pure chemicals were almost impossible to get, and his chances for accurate work were reduced to a minimum in many ways. Twenty-two years ago rule-o'-thumb and 'cut-and-try' were still helpful methods with a lot of us. Mr. Henrich's work, however, represented advanced thought and was very acceptable.

Discipline in Mines

The question of discipline in the management of mines will be of much greater importance in the future than has ever been attempted in the past. In my opinion it will be a vital factor in the safer operation of dangerous mines.

The fact that rigid discipline is maintained in European collieries is one of the open secrets of their steadily decreasing death rate from mine accidents. Yet despite this, the continental mines labor under more dangerous natural conditions than we have; their workings are deeper and more gaseous. For instance, England, France, Belgium, Nova Scotia and British Columbia mine coal in gaseous seams, on a scale as extensive as our own, and under conditions where they are surrounded with the maximum of danger; however, their statistics show a gradually decreasing percentage in the death rate; ours a shocking increase. This, more than any other argument, says something radically is wrong with our methods or management, or both.

We have often criticized our British cousins for their methodical ways, but the

writer is under the impression that it would be greatly to the general good of all concerned if we adopted a little more method and system in our work. We are altogether too restless, too experimental in our mining as in many other things. The child is ever unmindful to profit by the pitfalls encountered and overcome by the parent.

RESULT OF FOREIGN EXPERTS' VISIT

Not long ago the reader will recall the visitation of a committee of foreign mine experts, come hither at the solicitation of our Government, to look into mining conditions here with a view to offering suggestions for betterment. Their report was anything but startling. They told us but little we did not already know. The bulk of the commission's report is already embodied in many of our State mining laws. Some things they advised we do not at all approve. They suggested 650 volts of electricity as the limit in mines using that power, yet many of us have found to our regret that 250 volts is high enough considering the fatalities which have occurred from this source when men have come in contact with it. Taken as a whole, the commission simply told us that which we already knew, and left it to us to either change, or continue, as we saw fit, anything, which in our system was contrary to their finding; this confirms our opinion that it is up to us to adopt a system based on the best mining knowledge, and experience with actualities, and then strictly adhere to it.

THE LAWS MUST BE ENFORCED

Rigid discipline will be one of the chief essentials in the new methods which will undoubtedly be adopted. In the first place it will be necessary to have every employer and employee fear the law, insofar as violating it is concerned. It must be made financially easier for the employer, and less painful for the employee to obey the law than to ignore it. Employers of men must be taught by the sternest measures, that they must not expect an employee to be fire-boss and shot-firer, where one duty is enough to take all his time, and run chances of what may happen because of his inability to complete his contract. Employees must be taught in turn that they will have—even assuming no explosion follows their act—more time for their own pleasure if they get tamping clay by a little trouble, rather than use the more readily procured coal dust. Trivial things both, but what of the result? It does not seem so trivial according to Inspector Loutitt's testimony at a recent inquest.

PUNISHMENT SHOULD BE SEVERE

I can speak from personal experience when I say emphatically that the law is misconstrued purposely every day in many of our most gaseous mines, and even boldly violated without fear of punish-

ment. I have also found that the average miner has no fear, and seldom even respects the law as it relates to mining. This is a matter of vital importance to the safe working of our mines. Compare such a condition with the feeling that exists in other mining countries, England, for instance, where if a man leaves a ventilating door open, it means three months at hard labor without the option of a fine. And he gets it! Justice is meted out quickly and hard, whereas in this country the case would probably hang fire three months before being taken up by the court. I have spent a week of valuable time, with my work at the mine going by default, endeavoring to bring a case to argument where a miner had deliberately disobeyed the law. It is an experience which makes any mine official hesitate about enforcing the legal provisions governing his operation.

If we are to profit by any law, present or future, it must be enforced quickly, positively, and in such a way as will create a lasting impression; when this is done, mine managers will deem our laws a help, rather than a hindrance.

SIM REYNOLDS,

Superintendent Raven Coal Company,
Wheeling, W. Va.

January 6, 1909.

Speed of Hoisting at British Collieries

The speed of hoisting in British collieries is, according to an editorial note in the *South African Mining Journal*, Aug. 8, 1908, at the Dowlais Cardiff, 2220 ft. in 52 sec., an average winding speed of 2562 ft. per min.; Ashton Moss, 2850 ft. in 1 min. 25 sec., or 2010 ft. per min.; Lady Windsor, 1500 ft. in 35 sec., or 2571 ft. per min.; Bolsover, 1116 ft. in 28 sec., or 2388 ft. per min.; Denaby and Cadeby, 2289 ft. in 55 sec., or 2497 ft. per min.; Rhodes Rotherham, 1650 ft. in 45 min., or 2358 ft. per min.; while at the Rose-bridge mine a maximum hoisting speed of 5100 ft. per min. has been recorded; but this is excessive, as, for considerations of safety, it should not exceed 4000 ft. per min. From the foregoing data, and taking into consideration the needs of a regular output, an average hoisting speed of 3000 ft. per min. may be assumed to represent the best modern practice.

In timbered drifts the track should not be spiked directly to the sill timbers of the sets, as then it is difficult to lower the track if that becomes necessary in order to level it.

In mine tracks fish plates should always be used to join the rails, and the ends on both sides of the joint should be securely spiked.

Loading Blast Holes and Driving Small Drifts

By GEORGE C. McFARLANE*

Contributors to recent issues of the JOURNAL appear to hold widely divergent views as to the proper method of loading up the drill holes. As to the proper place for the detonating cap, I am certain that Mr. Adkinson is correct in stating that the hole shows more shattering in the vicinity of the detonating cap; this is no reason, however, for placing the cap in the bottom of the hole.

As everyone knows, dynamite is detonated from a solid into a gas by pressure. When the detonating cap lets go it compresses about 2 cu.in. of the surrounding mass of dynamite sufficiently to cause dissociation; the transition from solid to gas must occupy a definite interval of time, about one-twenty thousandth of a second. The initial explosion of one or two cubic inches of dynamite in the immediate vicinity of the cap would generate sufficient force to compress the entire charge to the dissociating pressure.

Detonation of a mass of black powder is effected by a uniformly expanding zone of flame starting from a spark. With dynamite detonation is accomplished with a succession of jolts separated by imperceptible but definite intervals of time. This explains why a strong cap and a well packed charge give definitely better results. The strong cap detonates enough of the surrounding charge to make a strong primary explosion. When the charge is well tamped the primary explosion would compress two or three feet of powder to the pressure of dissociation. With a weak cap and poorly compacted dynamite, it is conceivable that it might take three or four jolts to explode the whole charge.

The reason the ground around the primer is badly shattered is that the primary explosion of an ounce or so of dynamite hasn't power enough to spring the rock burdened on the hole, and as the tamping is tightly up against the explosive, the pressure crushes and shatters. In the interval that precedes the detonation of the main portion of the charge the gas from the primary explosion blows the tamping back an inch or so and cushions the main explosion to a certain extent. For these reasons I believe a cap should be in the top of a charge, because it is evident that the main or secondary explosion tears the rock out. With a cap on top a small part of the upper end of the charge is rendered useless for rock breaking purposes; with the cap in the bottom a small part of the bottom of the charge is consumed in shattering the bottom of the hole. With a lifter or back hole it wouldn't make a particle of difference, as far as breaking ground went, where the cap was;

with a cut hole, where the power is needed on the toe of the hole, a cap on top of the charge will tend to put the locus of the principal concussion a fraction of an inch nearer the bottom of the hole.

TAMPING

In breaking rocks with mud-caps, I find it makes a very material difference whether or not the detonating cap is placed on top of the dynamite. The most effective way to break a rock is to pick out a little depression and form a wall around it with plastic clay; fill this crater with dynamite, lay the cap on the center and cover the whole with soft clay. If the cap is shoved down into the dynamite the breaking power of the mud cap is lessened. The only possible explanation of this phenomenon is that when the detonator is near the bottom of the dynamite, the detonation lifts a portion of the explosive bodily from the rock before it bursts into gas. High explosives must have a good contact with rock which it is desired to break. When a mud cap is placed on top of a stone, the explosive is usually plastered down tight against it, and the stone is broken into several fragments; if the same quantity of explosive were poked under the stone it would have poor contact and do very little execution. This is the reason why dynamite is supposed to strike down.

In regard to tamping a hole, I think that ordinarily 8 or 10 in. of clay tamping is enough. Strong cut holes require more tamping to get the full power of the explosive. Take the case of a 6-ft. incut hole in the face of a drift, the hole being 1 3/4 in. in diameter and loaded with 32 in. of 60-per cent. explosive. The center of the charge would be burdened 4 ft. and in hard granite or trap it would take one two-thousandth of a second for the concussion to travel from the explosion to the free face. This means that for a period of one two-thousandth of a second the gases of the explosion must be confined. At the end of the period, the momentum imparted to the rock tears it away from the solid. During this period the tamping will be subjected to a pressure of 450,000 lb., sufficient to force 18 in. of clay or 3 ft. of water tamping 6 in. This shows that 18 in. of clay tamping is none too much. A 6-ft. hole burdened 30 in. would kick 8 in. of clay tamping back 6 in. before the rock cleaved from the solid.

A quick way to tamp up a round of holes is to have one of the muckers make a candle box full of clay slugs 1 1/2 in. in diameter and 4 or 5 in. long. In loading twist a piece of paper around one end of the slug and they are easily shoved in and rammed home with the loading stick. I think the best results are obtained by putting in 18 in. of tamping for the incut holes and 14 in. for the other holes. Using a 2 in. time interval on the fuses, the 10 in. in the fuse will be several inches in the tamping before an adjacent hole goes off. It is no uncommon thing for a hole

to kick off 2 or 3 ft. of another hole; as long as the fuse was burned down into the tamping and firmly bedded in a foot or so of clay, the spent fuse would break in case a collar blew off; otherwise the fuse might be pulled out of the hole. I noted a case in which one hole cut another hole off in the middle of the powder charge; the hole had pulled back to a slip and the dynamite was cut so smoothly that there was no sign of a hole on the slip until one of the men stuck his pick into it.

This cutting off of holes is a prolific source of accident. If the holes are overloaded as they often are, powder is thrown in the muck. Of course, there is no method of blasting that will eliminate accidents altogether, because things are liable to happen in blasting a round of holes that no man can foresee.

DRIFTING AND CROSSCUTTING

In driving drifts and crosscuts where there are no good slips or floors to break to, the "V" or pyramid incut will be found to be the most satisfactory. In narrow drifts four holes will be enough and they should be drilled so that the points nearly or quite intersect. In drifting, I think the double-screw column is much handier than a cross-bar, although it takes longer to rig up on a column than it does on a bar. In uneven ground, the machine often runs up or down on a hole; with a column and arm it is possible quickly to adjust the machine for alignment and often prevent the steel from fitching and running tight. In very tight, hard ground, it pays to set the column as close to the face as the machine will work; drill the holes about 5 1/2 ft., and give them as much lift as possible. Of course, when the cut holes are drilled with the machine close in, the column has to be rigged back about 18 in. to drill the back holes and lifters.

If the ground is only moderately hard it pays to drill the cut holes so as to bottom 1 3/4 in.; then four pounds of 60- or 75-per cent. dynamite can be put in the bottom 30 in. of each hole. If the ground is extremely hard, time can be made by drilling the holes smaller, bottoming them 1 1/4 or 1 3/8 in. Not only do small steels cut faster and hold their gage better, but it is also far easier to collar a hole on a slanting face with a small starter.

When small holes are used it will be necessary to spring the four cut holes with about four 1 1/4-in. sticks of 60-per cent.; then blow them out well with a blowpipe; this will chamber the holes so that they will take enough powder to throw out the incut. It takes about 40 min. to spring four holes, (15 min. to tamp up, 15 min. to get the smoke out of the drift, and 10 min. with the blowpipe to clean and cool the holes.)

ORDER OF FIRE AND MISFIRES

In most cases it is a decided advantage to blast the incut with a battery, although it takes more time than if the holes are

*Consulting mining engineer, Saginaw, Mich.

all loaded and fired in one round. When fired with a battery the cut generally kicks the collars off a few of the surrounding holes, so that after the incut round there isn't the same danger of holes cutting one another off and causing misfires and scattering powder in the muck. Again if the cut does not come out well the bottoms can be reloaded and spit with the squaring holes. When the incut is blasted separately, there isn't much danger of the machinemen lighting holes out of their proper order and perhaps spoiling the whole round.

If a hole that is solidly tamped with about a foot or so of clay tamping misses fire, it is certainly no joke to dig the tamping out. If the caps are always soaked, and waterproof fuse is used, such mishaps are bound to be extremely rare. One method of drawing tamping that is a little safer than picking it out with a scraper, is to burn it out by repeatedly loading up whatever collar there is to the hole; after two or three shots the concussion will jar through the tamping and set off the main charge. Another method, which I believe is safer, is to make a little tank by capping both ends of a 6- or 8-in. pipe about 3 ft. long, tapping in a couple of inch nipples on opposite sides of the pipe. This tank would hold two or three pails of water. To blow tamping use a small tip on the blowpipe, wedge a plank or board across the drift, and after inserting the blowpipe in the hole, lash it fast to the board so that it cannot kick back. Now run the blowpipe hose to the water tank and run the machine hose from the air pipe to the upper nipple of the tank. Use a valve two or three hundred feet back from the face for turning on the air pressure. This method works well in an upper or flat hole; it will often wash out a foot of tamping without shifting the blowpipe.

Indiana Mine Legislation

SPECIAL CORRESPONDENCE

The indications point to considerable legislation relating to mines and miners in Indiana during the present session. At first opportunity, three bills were introduced. Senator Bland presented a bill to regulate the width of entrances to coal mines. Senator Roysse introduced a bill which provides for the careful supervision of men who work in the coal mines of the State. This measure provides for the creation of a miners' examining board in each county where mining is carried on. Said board is to consist of three members appointed by the circuit judges of the different counties who shall hold examinations monthly, keep a record of the mining certificates issued and make stated reports to the circuit judges, and to the mines inspectors of their respective districts. No

man will be entitled to work in the mines, who has not had two years' experience in such work, and all who have been in the work two years will be entitled to certificates without examination.

There is nothing in the bill which will prevent men from working under the direction of skilled miners in order that they may learn the business. The measure calls for a fine of from \$100 to \$500, or a sentence in the county jail from 30 days to six months for violation of any of the provisions of the act.

Coal Miners' Convention

SPECIAL CORRESPONDENCE

A large number of the 1100 delegates due to attend the International Convention of the Mine Workers of America, in Indianapolis, Indiana, beginning Jan. 19, were on hand the day before the convention opened. Already there are hints among the delegates and at headquarters of exciting times ahead, and even President Lewis intimates that he will not be at all surprised if the convention is the stormiest ever held.

Much interest centers in the outcome of the election for president, and a few anti-Lewis men are saying that, in the event Lewis carries the day, several districts are almost certain to secede.

The friends of President Lewis contend with some show of reason that he has not had a "fair shake," and assert openly that a systematic effort has been made to cripple his administration. They point to the fact that he succeeded in reviving the joint conference after it had become, to all intents and purposes, dead; that he secured a two-year wage scale during a panic, which continued in force the "prosperity" scale of wages for 285,000 mine workers, a thing unprecedented in the history of joint conferences; that in reviving the joint conference he practically saved the organization from dissolution, as all well-informed union men assert, that without the presence of the employers at a convention there is no one to negotiate with.

On the other hand his opponents say he has lost every strike and abandoned districts in trouble until several vice-presidents have refused to longer serve as national officers.

To those who stood at the cradle of the organization and risked much to make it the most powerful trades union in the world, the situation is particularly distressing. They are hopeful some course will be pursued that will avert the threatened rupture, for they say it is idle to deny that the organization now faces the most critical period in its history; that it is divided into factions which are arrayed against one another with undisguised hostility.

The anthracite situation does not present a roseate appearance, from the organization's point of view. The fact is the union is in a moribund condition with a pitiful sum in the three district treasuries, compared to what should be there to meet what will be a most serious situation in April, when the three-year contract will expire by limitation. The outlook, therefore, for a successful struggle with the anthracite operators does not seem particularly hopeful to even the most sanguine.

Other matters known to be antagonistic to the Lewis administration are to come up, which will tax the conservative members heavily to prevent continued dissension and strife during the convention.

Mining Legislation at Washington

SPECIAL CORRESPONDENCE

The bill for the relief of applicants for mineral surveys (H. R., 25,396) introduced on Jan. 8 by Representative J. C. Needham and referred to the House Committee on Mines and Mining was favorably reported on Jan. 14. A few amendments were incorporated and the measure now reads as follows:

"That the Secretary of the Treasury be, and he is hereby, authorized and directed to pay, out of the moneys heretofore or hereafter covered into the Treasury from deposits made by individuals to cover the cost of work performed and to be performed in the offices of the United States surveyors-general in connection with the survey of mineral lands, any excess in the amount deposited over and above the actual cost of the work performed, including all expenses incident thereto for which the deposits were severally made or the whole of any unused deposit; and such sums, as the several cases may be, shall be deemed to be annually and permanently appropriated for that purpose. Such repayments shall be made to the person or persons who made the several deposits, or to his or their legal representatives, after the completion or abandonment of the work for which the deposits were made, and upon an account certified by the surveyor-general of the district in which the mineral land surveyed or sought to be surveyed is situated and approved by the Commissioner of the General Land Office."

The amendments are of importance because they make the bill apply for the future as well as to past transactions, while the appropriation is made annual and permanent with this purpose in view. The changes were introduced in consequence of a letter from First Assistant Secretary of the Interior Frank Pierce to Mr. Needham, in which Mr. Pierce pointed out that the proposed legislation was urgently needed, as the sums which

accumulate in consequence of these deposits are neither funds of and available to the United States, nor, under present conditions, repayable to those rightfully entitled to them. He went on to note that the Comptroller of the Treasury disagreed with the conclusion reached by the department (36 Land Dec., 561) in a case of an application for such repayment, upon the ground that while Section 2402, Revised Statutes, directs repayment of "any excess in such sums over and above the actual cost of the surveys," it does not in terms appropriate them to that purpose, which appears to be a strict rule of interpretation in his office. The effect of the bill as now drafted will be to bring about the regular repayment of unused deposits and the excess of deposits made by individuals to cover the cost of work in the offices of surveyors-general and covered into the Treasury in connection with mineral surveys.

Tariff Hearings at Washington

SPECIAL CORRESPONDENCE

It has become apparent within the past few days that the Ways and Means Committee is making a serious study of the question of duties on iron ore, and is inclining to the idea of removing them entirely, or at least making a large cut in the present rates. Chairman Payne has carried on considerable correspondence with reference to the metallic content of various ores and has written to some of the producers to ask the character and fine content of their product. In addition he has written to the Geological Survey asking for a tabulated statement showing the content of a number of domestic and foreign ores. This has been furnished him, the answer giving, including Lake, Alabama, Cuban, Spanish and Newfoundland ores. Chairman Payne has particularly written to some of the iron-ore interests who appeared before the committee some time ago in order to get their views. A poll of the Republican members of the committee has shown that they are nearly evenly divided on the subject of removing the tariff on iron ores and that evidence one way or the other that would suffice to turn a single vote might alter the whole outcome on this topic and with it change the general range of duties which will be assessed upon iron and steel products. Among the marked developments in this connection during the past few days has been the definite alignment of the Pacific Coast interests both northern and southern in favor of the total removal of the duty on pig iron, iron ore and coke, strong demands being filed with the committee from Pacific Coast sources, including the United Metal Trades Association of Portland and the Founders' and Engravers'

Association of Los Angeles. Severe pressure from New England consumers of scrap iron has also developed a request that the tariff be removed, or else cut to not over \$1 in place of the present rate of \$4 per ton.

ZINC ORE

Along with the iron-ore question the Ways and Means Committee is seriously considering the tariff treatment of zinc ore. The question of duties on the ore is among the most hotly contested that has yet been presented to the committee, and a large number of briefs has been filed on both sides of the question. The opposition to the proposed duties has become exceptionally strong within the past 10 days and is being voiced both by consumers and the smelting interests.

The position of the smelting industry is that there is a constantly increasing shortage of the raw material, and if domestic consumption of spelter is to increase in the same ratio the next 10 years as it has in the past 10, the whole industry will be confronted with a disastrous condition if deprived of foreign ores. Instead of these ores coming to the United States under a duty, it is alleged that they would go to foreign countries, and the users of spelter would be compelled to supply a part of their requirements with the foreign article. It is argued that the domestic production of zinc has increased within the last 10 years 100 per cent., whereas the Joplin district has only been able to increase its output a scant 10 per cent. during this time. The zinc smelting industry is said to be facing a shortage of raw material, even with the ores of Mexico and British Columbia. Some interests urge that it would be better to reduce duties on spelter than see a duty placed on raw material, and 1c. a pound on finished spelter is said by them to be ample to give the American miner and smelter all the protection they are entitled to. It is pointed out that the difference in the average price in London and the average price in New York during the past 10 years has been less than 0.75c. a pound.

The Cape Copper Company

SPECIAL CORRESPONDENCE

The Cape Copper Company, Ltd., has issued a report for the year ended Aug. 31, 1908. The net profit amounted to £144,366, which is a long way below that earned in the previous year. This large decrease is principally to be attributed to the lower prices that have ruled for copper during the year under review. The decrease in profit has reduced the dividend on the ordinary shares from 19s. per share in 1907 to 8s. 6d. per share in 1908. The company dates from 1888 and is a

reconstruction of the Cape Copper Mining Company, Ltd., registered in 1803, which paid dividends amounting to £1,324,375 between 1864 and 1888, or £67 13s. 9d. per original £10 share, on which £8 per share were paid. The present company has distributed between 1889 and 1908 £2,666,250 to the ordinary shareholders and £336,150 to the preference shareholders. The operations of the company are not confined to South Africa; it is also interested in the Tilt Cove Copper Company in Newfoundland, as well as in copper mines in India and America. In the two latter countries, however, the operations are of an experimental character.

In South Africa the principal mines are the O'okiep and Nababecp mines, the output from which has been practically the same as that returned in the preceding year. From the O'okiep mine 14,812 dry tons of 15.02 per cent. copper were mined, while from the Nababecp mine the output was 54,974 dry tons of 4.78 per cent. copper. The reserves of ore at the O'okiep mine are estimated at 10,000 tons of 20 per cent. copper ore and at Nababecp 150,000 tons of 5 per cent. ore. From the Nababecp North mine 5069 tons of 5.83 per cent. copper contents were mined. The company owns smelting works both in the Cape Colony and at Britonferry, in England.

At the O'okiep smelting works 25,586 tons of ore were treated, the matte produced averaging 51.2 per cent. copper. At the Nababecp works 51,872 tons were smelted, the matte obtained averaging 49.7 per cent. copper. No details are given in the report about the operations at the smelting works at Britonferry, the only information given being that results have been satisfactory, and that further improvements to the plant have been carried out during the year.

In Newfoundland the Tilt Cove establishment made a profit for the year ending Dec. 31, 1907 of £51,034, one-half of which was paid to the Tilt Cove Copper Company and the other half was credited to the profit and loss account of the Cape Copper Company. The output from the East mine was 27,062 tons of 3.3-per cent. copper, wet assay. The South Lode returned 12,961 tons of 3.53-per cent. copper. The ore reserves at the East mine and the South Lode are given as 45,756 tons.

The director's report is supplemented by several detailed departmental reports.

As regards the South African interests there are no less than 11 separate reports, namely those of the superintendent, the chief mine agent, the mines mechanical engineer, the railway engineer, the traffic manager, the smelting works manager, the port and shipping manager, two medical officers and of two chaplains. These reports are eloquent of good organization and show that the company pays attention to the well-being of its employees.

Personals

Mining and metallurgical engineers are invited to keep **THE ENGINEERING AND MINING JOURNAL** informed of their movements and appointments.

J. E. Spurr is at Matehuala, San Luis Potosi, Mexico.

J. M. Callow, of Salt Lake City, Utah, has been at Ely, Nevada.

H. W. Turner, of San Francisco, is engaged on professional work at Jean, Nevada.

Charles W. McPherson, inspector of surveys in the Canadian Yukon, is on his way to Scotland.

A. Kunkle has been appointed superintendent of the Iowa-Tiger mines, near Silverton, Colorado.

R. Alvin Weiss, of New York, mining engineer, has been called to Montana on professional business.

We shall be obliged if H. B. Pulsifer, formerly of Kansas City, Mo., will advise us as to his present address.

Joseph Jacobson, manager of the Columbus Consolidated mines, Utah, has been a visitor at Houghton, Michigan.

M. M. Johnson, of Salt Lake City, engineer for the Newhouse interests, has been examining claims at Seven Troughs, Nevada.

H. F. Seymour, of Cleveland, O., has taken charge of the Great Southern Mica Company, with headquarters at Asheville, North Carolina.

Dr. Henry Froehling, of Richmond, Va., has been examining the Catawba gold mine, near Kings Mountain, N. C., for Richmond buyers.

Duncan McVichie, of Salt Lake City, recently examined the Prince Consolidated and Ohio-Kentucky mines at Pioche, Nev. He went from there to Tonopah.

Mark B. Kerr, of San Francisco, has been appointed consulting engineer for the Pittsburg-Gold Flat Mines Company in the Grass Valley district, Nevada county, California.

Elton W. Walker has resigned his position as superintendent of the Tombstone Consolidated Mines Company in Arizona, to take effect Feb. 1, and will open an office in Detroit, Mich., as consulting engineer.

The firm of Harvey & Wilbraham, consulting mining engineers, London, England, has been formed by F. O. Harvey, of London, and A. G. B. Wilbraham, late manager of the mining department of Mason & Barry, Ltd., in Portugal.

Edward H. Taylor, Harry W. Weeks, W. D. Stuckenberg and B. G. Maynes have established an office as consulting fuel engineers and chemists, in the Old Colony building, Chicago. The business will be conducted under the name of the Com-

mercial Testing and Engineering Company.

Charles F. Huber has been appointed vice-president and general manager of the Lehigh & Wilkes-Barre Coal Company, with office at Wilkes-Barre, Penn. He has been with the company for 21 years, acting successively as division engineer at Audenried, as chief mining engineer and as general superintendent.

Last winter J. B. Tyrrell, of Toronto, Ont., offered a prize of \$100 for the best collection of minerals to be made in the Province of Ontario during the summer of 1908. Professor Nicol, of Kingston, and Professor Walker, of Toronto, examined the collections and awarded the prize to W. F. Battersby, a third-year student in the School of Mines, Kingston, Ont., who collected most of his minerals in the Montreal River district in Ontario.

Obituary

B. Franklin Jones, superintendent of the Westmoreland Coal Company in Pennsylvania, died Jan. 15, at Atlantic City, N. J., where he had gone for his health. He was 45 years old. He was formerly with the H. C. Frick Coke Company, rising to the position of division superintendent at Uniontown. In 1903 he left that place to take charge of the Westmoreland Company's mines. He was an active member and president of the Coal Mining Institute of America.

Alexander McDonald, a pioneer of the Yukon, died suddenly of heart failure at Celar Creek, Yukon Territory, on Jan. 6, at the age of 52 years. Mr. McDonald was a native of Nova Scotia and reached Dawson in 1896, taking up claims in the Klondike. He speedily amassed a fortune estimated at \$5,000,000. He was considered the richest man in the Territory and was also heavily interested in Alberta coal lands. The body was taken to Vancouver for interment.

Alexander Thomas, secretary of the Crucible Steel Company, of America, died Jan. 8, aged 59 years, at Hamburg, Germany. He went to Germany last August in the interest of the company. For more than 30 years Mr. Thomas was identified with the crucible steel industry, having been connected with the Park Steel Company prior to its amalgamation with the Crucible Steel Company of America. Two years ago he visited Japan and did much to introduce American steel in the Orient.

Almarin B. Paul, one of the oldest pioneer miners of California, died in San Francisco on Jan. 12 at the ripe age of 85 years. Mr. Paul had been in active mining ever since he arrived in California in 1849. He built the first quartz mill in the State and was also one of the first to take up the cyanide process on the Pacific coast. He began early to investigate

the values to be found in the black sands of the ocean beaches and of the hydraulic mines. For a great number of years he contributed largely to the local technical press on the subject of saving fine gold in the quartz and placer workings, and became an enthusiast on the subject. He was one of the earlier miners on the Comstock lode in Nevada, having gone there at once on the discovery of gold, but eventually returned to California. In earlier days he visited all the mining excitements on the coast and in this way acquired a great amount of practical knowledge and a wide acquaintance. He was a constant investigator of metallurgical processes connected with gold and silver mining. For the past 10 years or more he had confined his attention to his mining interests in the quartz properties in Shasta county. Mr. Paul was an enthusiastic advocate of the mining industry of California and was well known all over the State.

Societies and Technical Schools

Institution of Mining Engineers of Great Britain—The office and headquarters have been transferred from Newcastle-upon-Tyne, England, to 39 Victoria street, London.

Massachusetts Institute of Technology—The electrical engineering courses are now attended by a number of graduate students, who are pursuing the advanced courses offered. The electrical department needs larger quarters, and it is hoped that they will soon be provided.

Iowa Engineering Society—This society held its 21st annual convention at Waterloo, Iowa, Jan. 13 and 14. The following are the officers for the ensuing year: President, C. T. Wilson, Waterloo; vice-president, T. R. Warriner, Cedar Rapids; secretary and treasurer, A. H. Ford, Iowa City; directors, L. H. Stone, Cedar Rapids and C. P. Chase, Clinton.

Indiana Engineering Society—The twenty-ninth annual convention of the Indiana Engineering Society was held in Indianapolis, Jan. 14, 15 and 16. Professor W. K. Hatl, of Purdue University, is president and Charles Brossman, of Indianapolis, secretary. The program for the present convention was unusually full of interesting subjects, which were discussed by prominent men. The committee on mining consists of C. J. Colgan, Linton; Frank A. Kaffman, Brazil; P. B. Breneman, West Lafayette. Mr. Colgan made a report on conditions of the Indiana mines and mine engineering, Jan. 15. A report on "Comparative Tests of Indiana Coal" was made by Prof. C. A. Young, of Lafayette. George W. Munroe gave an illustrated lecture on "Producer Gas from Indiana Coal." The meeting closed with a banquet and other social features were introduced.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at
San Francisco, Butte, Goldfield, Salt Lake City and Denver

REVIEWS OF IMPORTANT EVENTS

San Francisco

Jan. 11.—The Natomas Consolidated, of California, the new corporation which has acquired extensive dredging interests both at Folsom and Oroville, intends utilizing all the rock piles thrown up by the numerous dredges by crushing the cobbles into road-making material. After removing the cobbles the land left is suitable for agricultural operations, and thus one of the objections to the dredging industry may be removed. The company owns certain valuable water rights, and has obtained options on about 50,000 acres of land which is to be brought under irrigation and sold to settlers. This land has been more or less subject to overflows, and will be reclaimed and made fit for cultivation. The water used for power purposes can be later used for irrigating this large tract of land in Sacramento county.

The Anti-Débris Association has also succeeded in bringing the dredge miners into line in some measure. A committee was appointed to visit the Oroville dredging field and determine whether suit could be commenced against the dredge owners. The Dredge Miners' Association has now written to this Anti-Débris Association committee, agreeing to comply with all the demands and promising that no material should be allowed to reach the Feather river. The Anti-Débris Association has usually whipped the miners in any litigation, and doubtless the dredge miners want to avoid litigation if it is a possible thing.

The current at the Big Bend plant of the Great Western Power Company has been turned on for the first time. At the start some 50,000 h.p. will be generated, to be increased later on to 100,000 h.p. The lines have been carried complete from Big Bend in Butte county as far as Oakland, on the bay shore.

A new schedule of rates on ore will be adopted on the Tonopah & Tidewater railroad on Jan. 24, which will have a marked effect on mining affairs both in this State and Nevada. The reduction will admit of handling ores which are at present of little or no value, as they cannot be shipped to smelters. A better profit can also be made by the miners on ores of the character now being shipped. The new freight tariff will also probably have the effect of sending more ores to the smelting plant at Needles, San Bernardino county, and somewhat less to the smelters on San Francisco bay. The new tariff shows an entire readjustment on rates

of varied grades of ore. The Tecopa district in Inyo county, where much lead ore is being mined, pays a flat rate now of \$8.89 per ton on ore from \$50 to \$100 in value. Under the new rate \$60 ore will pay \$4.95; \$70 ore, \$6.45; and \$100 ore will pay but \$8.20. On the lower grades from Tecopa district the rate on \$15 ore is reduced from \$2.61 to \$2; and on \$40 ore from \$3.98 to \$3.25, and the intermediate grades in proportion. The new rates from Goldfield cut the charges from \$2.60 on \$40 ore to \$2.75 on \$15 ore. The rates from Rhyolite and Beatty districts are cut also, and are from 50c. to \$1 less than from Goldfield. These rates should change shipments from Salt Lake and San Francisco to Needles and will benefit the different mining camps along the line of the road.

In this connection it may be stated that merchants and manufacturers and others in this city are making a determined fight against the proposed higher east- and west-bound freights on the transcontinental railroads. An organization has been perfected and the shipping community is pulling together.

The second furnace of the new copper-smelting plant at Coram, in Shasta county, has been blown in, and the converter plant will be ready for operation in a few days.

The Leona Chemical Company has issued bonds to the amount of \$1,000,000, and will now greatly enlarge its chemical manufacture plant at Melrose on San Leandro bay. The company will manufacture industrial chemicals from raw materials taken from its own mines. The pyrites deposit at Laundry Farm will give the materials for extensive sulphuric-acid making, and the barytes mine in Mariposa county will furnish the ore for making paint materials. A number of minor products will also be turned out. Roland L. Oliver, of Oakland, is general manager, and F. M. Smith is largely interested.

Goldfield, Nevada

Jan. 12.—At the annual meeting of the Goldfield Consolidated held yesterday at Evanston, Wyo., several changes were made in the directorate of the company, which now stands as follows: Senator George Nixon, president; George Wingfield, vice-president; W. C. Ralston, of San Francisco, treasurer; J. M. MacKenzie, manager, Charles Hayden, of Boston, J. H. Cartairs and J. D. Hubbard, directors. John S. Cook, James R. Davis and J. M. Fenwick are the retiring direc-

tors; the latter to act as private secretary for George Wingfield. Dividends of 30c. per quarter are to be resumed on March 1; this will mean a quarterly distribution of \$1,080,000.

Davis & Loftus, who have taken over the property of the Bullfrog Gold Bar Mining Company, have submitted to the stockholders a plan of reorganization and are desirous of obtaining the name and address of every stockholder in the company that they may present to every one the outline of this plan.

While little is heard of the Gold Mountain district, there is a large amount of development work being carried on. The Bonnie Clare Mining Company which is prospecting the May Day lode by an adit is meeting with encouraging results. This property was closed down a year ago due to dissention among the principal stockholders, who allowed the company to go into the hands of a receiver; the receivership has since been dissolved. A large amount of supplies have lately been shipped into the old Oriental mine in that district, and extensive development work is to be carried on. It will be remembered that some of the finest specimens of gold ore ever exhibited came from this property; this ore is now in the museum of the Smithsonian Institute at Washington.

Unfortunately, this district has suffered in the past by poor management of its properties and the greediness of mining promoters, but with good economical management and better milling facilities, many of the properties now idle can be made paying propositions.

A contract is to be let shortly for the construction of a telephone line from Tonopah to Helena, the new town near the Broken Hills mine, and about 40 miles east of Tonopah.

The Champion traction engine, built to haul 20 tons of ore from the Great Western mine at Hornsilver to its shipping point, Cuprite on the Tonopah & Tidewater railroad broke down on its initial trip last week. New parts were ordered, and mule teams are being used until these parts arrive.

L. J. Cohn, register at the Carson City land office, reports that during the month of December 125 final mineral entries were made on mining claims, involving payments of nearly \$30,000 by the claimants.

The Western Ore Purchasing Company, whose plant was destroyed by fire at Hazen last week, has purchased the old

Scott & Amann sampler at that place and will use it while a new plant is being erected. The sampler of the Western Ore Purchasing Company at Hazen, Nev., was totally destroyed by fire Jan. 3, the loss being in the neighborhood of \$60,000, partially covered by insurance. At the time of the fire there was about 1500 tons of ore stored in the bins, which will be shipped to Salt Lake City for sampling. The plant will be rebuilt at once on a larger scale.

The Nevada Bay State Oil Company, which has been drilling for oil in the salt marsh northwest of Goldfield but was compelled to stop operations due to the cable's breaking, has received a specially designed fishing apparatus from Los Angeles, and will endeavor to recover the cable. The well is 500 ft. deep.

The sulphur mine at Cuprite, 15 miles south of Goldfield, shipped four carloads last week, and it is reported that this amount will be shipped to Los Angeles each week.

The old camp of Candelaria, in the northern part of Esmeralda county has taken its place again on the shipping list. Last week the Potosi Mining Company made a shipment of 175 tons of ore to the smelter at Bingham Junction, Utah.

Owing to the financial depression during the past year, a number of mining companies and many individual claim holders neglected performing the annual labor prescribed by law on their lode claims, which technically amounts to abandoning the same. As a result on Jan. 1 a great many re-locations were made throughout the State.

By means of an injunction Horton and Aldrich, of Chicago, have secured a postponement of the annual meeting of the Little Florence until Jan. 20. The meeting will no doubt be a lively one as the feeling between the two factions is very bitter, and sensational charges have been made by both sides.

Salt Lake City

Jan. 15—Twenty-two cars of machinery for the Ohio Copper Company's mill arrived at Lark during the week. The jigs are already in place, but the slimmers and tables have not arrived. The last shipment consists mainly of transmission machinery—transformers, shafting, pulleys, belting, etc. The raise from the Mascotte tunnel to connect with the shaft of the Ohio Copper Company is progressing rapidly so that connection should be made by the end of February.

At Garfield the Fink furnace is said to be meeting with considerable success in making high-grade matte, but owing to trouble with the furnace lining as yet no attempt has been made to make blister copper directly from the ore. An automatic feeder is being installed, and it

is said that as soon as that is in place the attempt to make blister copper will be made. Samuel Newhouse is so greatly pleased with the Fink experiments that he has announced that the Cactus mine will be equipped with a 300-ton Fink smelter even if the furnace fails to make blister copper.

It has been demonstrated that the plant can make matte carrying as high as 70 to 80 per cent. copper successfully and rapidly, and it is claimed that within a short time the furnace will be turning out blister copper with the same ease with which it is now producing matte. The plant consists of two revolving cylinders which smelt and roast alternately, the smelting cylinder generating gases which are utilized as fuel in the roasting cylinder. In starting the process some coal is required, but once in operation the sulphur gases do the roasting. Both the roasting and the smelting of the concentrates is accomplished with a single fuel charge, and the cooling of the calcines is avoided. Furthermore the fumes are caught and do not enter the stacks. When the concentrates have been converted into matte the slag is drawn off and a charge of silica added in order to reduce the ferrous oxide. The matte is kept agitated by the revolving cylinder and by forcing air into it converted into blister copper. The plant is very inexpensive compared with the ordinary smelting plant, and is extremely simple.

Butte

Jan. 14—The continued cold weather which has prevailed throughout the State for the past two weeks has seriously affected the output of the Butte mines. For the past week the Boston & Montana smelter at Great Falls has been operating at about one-third its normal capacity. This is due partly to the diminished water power caused by freezing of pipes, but chiefly to the fact that the ore in cars shipped from Butte is frozen solid during the journey and the only way to get it out is to mine it over again. The greater part of the Great Northern railway's ore cars are now at Great Falls loaded with ore which it is impossible to remove. As a consequence there is a car shortage in and around Butte, and the mines of the Boston & Montana company, which ship to the Great Falls smelter, have been closed down since last Friday. Owing to the peculiar cause of the shutdown it is not known just when shipping will be resumed. At the Washoe smelter at Anaconda no trouble has been experienced with frozen ore. This is because of the shorter haul for the ore and also because at the Washoe plant the cars are immediately run into drying sheds, where a sufficiently high temperature dries out the ore and loosens it.

At the annual meeting of the Montana Society of Engineers, held at Great Falls

last week, C. H. Bowman, of Butte, president of the Montana State School of Mines, was elected president of the society for the ensuing year. Steps were taken toward obtaining favorable legislation for the proper supervision of the county roads, a committee being appointed to confer with the members of the legislature on the subject.

The British-Butte Mining Company has instituted action against the owners of adjoining claims for the purpose of obtaining the right to run ditches so that the company's new gold dredge may be operated. The company alleges in its complaint that it has erected a gold dredge upon its property at a cost of \$80,000, and that unless it can obtain the right to run the ditches the new dredge will be valueless.

Denver

Jan. 16—The most lively topic of discussion in mining circles at the present time is the anticipated advent of the new independent smelting company into the mining districts of the West. This company, with \$50,000,000 capital, is said to be backed by the Standard Oil, Amalgamated, Ryan-Cole, and allied interests. It is confidently expected to commence the erection of a large copper plant near Salt Lake City at an early date.

Now comes the resignation of Dennis Sheedy from the board of directors of the American Smelting and Refining Company, and a strong rumor that he is going on the board of the new competitive company, with the further inference that the new company is going into the lead-smelting business in this State, in active competition with the American company at the latter's own exclusive game.

The mineowners are, of course, pleased to learn of the entry of another "Richmond in the field," with the possibility of a sanguinary struggle, and slashing of treatment rates right and left.

Such, then, are the points of active discussion in mining circles at the present time. To people conversant with the mining and smelting situation in Colorado the question arises, "Where will the ore be obtained?" and particularly lead and fluxing ores, on which the American Smelting Company has for some time yet exclusive call. Colorado is a great mining State, and with the material lowering of treatment charges, the output of low- and medium-grade ores will be greatly stimulated, and there is a strong possibility that the new company, starting in the smelting business with ample capital and modern works, carrying only the actual cost of construction, paying nothing for good will of a former business, and not saturated with water, will find an ample and profitable field in this State, to the great advantage of the mining community as a whole.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Arizona

GRAHAM COUNTY

Arizona Copper—A loss of about \$200,000 was caused by fire at the smelter due to a runaway slag train. Concentrator No. 2 is a total wreck, while the engine room, smelter, ore and coke bins, were badly damaged.

Kentucky—A strike of copper glance is reported at a depth of 225 feet.

New York-Arizona—During the past two years \$24,000 has been spent in development work. Most of the work is being done in the Lillian tunnel which is 1000 ft. long, and has attained a depth of 300 ft. Four hundred feet more work in this tunnel will tap shafts from which ore shipments have been made. A compressor is being installed. The water supply is from the pipe line of the Morenci Water Company.

Gold Belt—About \$18,000 worth of copper ore was shipped during 1908. Operations will be resumed at once.

Morenci Water Company—A steel bridge has been built across Eagle creek. It is a one-span trestle 187 ft. long and 14 ft. above the river bed, and is for the purpose of holding the heavy 10-in. pipe line out of danger of high water during the flood season. Heretofore the pipe line was under the ground, but this was very unsatisfactory as the floods invariably broke and injured the pipes.

PINAL COUNTY

Ray Consolidated—Plans are being drawn for a large reduction plant, work on which will begin about the middle of this year. Eleven prospecting drills are at work and ten acres have been prospected during the past month, proving low-grade copper deposits.

California

AMADOR COUNTY

Central Eureka—The shaft has been timbered to below the 2000-ft. level, but bad air has given some trouble.

South Eureka—Another assessment has been levied on the stock of this company. The stockholders are persistent, for they have been paying assessments off and on for about 20 years with only an occasional profitable orebody.

CALAVERAS COUNTY

Eastland-Groy—This gravel mine has been sold to S. R. Fox who intends work-

ing it by some dredging system. The mine is near San Andreas and operations have been resumed.

Finch—Active work has been commenced on this Angels Camp mine. A body of ore on the 600 level is to be worked.

EL DORADO COUNTY

Garden Valley District—A. R. Seymour has leased, with the privilege of purchase, 20 acres of mining ground in this district and has begun operations upon it.

INYO COUNTY

Monster—The first shipment of ore under the new management has been made by this mine to the smelter at Keeler. The ore runs high in lead with considerable silver. A. A. Stanton, of Los Angeles, is manager.

KERN COUNTY

Farricac—The quartz mill of this mine near Rosamond is nearly ready to be started.

MARIPOSA COUNTY

Hornitos—A new mill, quartz crusher, etc., for this camp is now being hauled in from the railroad. Considerable prospecting is going on in that locality.

NEVADA COUNTY

Bear River—Arrangements are being made by the owners to bond this mine to Eastern men. They have been working the tunnel for two years and while a 2-ft. ledge has been found, there is no pay ore as yet.

PLACER COUNTY

Long Beach Asbestos Company—This company, of Long Beach, Los Angeles county, intended to manufacture helmets, and coats for firemen and other articles from the asbestos found near Towle. Thos. E. Morgan, of Dutch Flat, however, on the last day of the year relocated the asbestos claim on the ground that work had not been done on them in accordance with the law.

PLUMAS COUNTY

Rose Quartz Mining and Milling Company—This new company intends working the group of seven claims owned by F. H. Kelley on Poormans creek, in Onion Valley district. The claims are only partly developed. F. H. Kelley and O. C. Pratt, of Quincy, are among the incorporators.

SIERRA COUNTY

Dead Broke—The White Bear Mining Company is about to reopen the old tunnel on this mine. The ledge carries large quantities of sulphurets which were laid aside in early-day mining but are now valuable.

SISKIYOU COUNTY

Hardscrabble—This company at China Gulch has purchased a gasoline engine for power purposes.

Quartz—A new company has taken hold of the group of quartz mines owned by Foster & Mackintosh at Nigger Creek, near Callahan.

TRINITY COUNTY

West Point—Mark Manley for this company has bonded the Leas and Nicholson mines which adjoin the Brown Bear property at Deadwood. There are five claims.

TULUMNE COUNTY

Harvard—Fifty of the 60 stamps of the mill at this mine are dropping and the other 10 will be put in use as soon as the concentrators are installed.

Tarantula—This mine near Chinese has been sold to C. F. Crawford representing English capitalists, by Joseph Russell; an air compressor and machine drill have been ordered.

Colorado

BOULDER COUNTY

Alton—Kansas City and Chicago men are interested, and they will get plans for the erection of a milling plant. W. R. Burke, Boulder, Colo., is manager.

Mount Audubon Power Company—This company is going to build a hydroelectric plant at its property, expecting to generate about 1500 h.p., the estimated cost of the complete plant to be \$75,000. J. E. Haggard, Ward, Colo., is manager.

Rip Van Dam—Denver people have purchased one-half interest with William Brown at Springdale, Colo., and heavy developments are being mapped.

CLEAR CREEK COUNTY

Limu Consolidated—An air compressor is being installed at the property near Georgetown.

Pioneer & Monitor Group—P. W. McCaffney, of New York, has purchased these groups near Dumont, the consideration being reported at \$150,000, on which

a cash payment of \$25,000 was made. New and heavier machinery is to be installed and an electrochemical process will be tried in the mill.

Santiago—It is reported that in the spring this company will arrange for the erection of an aerial tramway from the mine to its mill at Georgetown, a distance of three miles.

Snowdrift—Nashville, Tenn., people are interested in the purchase of this group, and they will develop their holdings through the tunnel, near Georgetown, as the Snowdrift Mining Company.

Vidler Tunnel—After an idleness of over a year a contract has been given to F. A. Goetz, of Georgetown, for the driving of 200 ft. on this tunnel in the Argentine district.

LAKE COUNTY—LEADVILLE

Banker Tunnel—This tunnel, Winfield, is in 4000 ft., and for several hundred feet has been driven through a mass of low-grade ore. A few days ago a streak of ore came into the low-grade body which runs high in gold, silver, copper and lead. This ore is being sacked. The manager of the property is at present East consulting with the stockholders as to erecting a mill in the spring to treat the low-grade ore. The principal stockholders are in Philadelphia, with Doctor Horner, of that city, as president of the company.

Cleveland—Sinking has started on this mine, South Evans gulch, and the shaft will be sent down another 100 ft.; good progress is being made with the work, as there is little water to handle, not over 25 gal. a minute.

Gallagher—The new shaft on this property, to the north of the original shaft, has opened ore carrying some gold and silver and a large percentage of lead. Ore is being shipped from the old shaft steadily.

Helena—The station at the 700-ft. level, Iowa gulch, has been cut and a new pump is being installed; it is large enough to handle the flow of water easily, so that the next 100 ft. of sinking will be easily accomplished. With every foot of sinking the formation changes and the management looks for the orebody before the contract is completed.

Progressive—The body of ore recently opened in this mine, North Fryer hill, is now 9 ft. high and 7 ft. wide, with top and bottom not reached. Shipments are going out steadily.

Vinnie—High-grade gold ore is being taken from this claim, Breece hill. The streak of this rich matter is in a body of medium grade ore. The vein runs into the Ibex ground about the tenth level.

Young America—The owners of this mine, Granite, state they have on the dump 15,000 tons of ore that will average \$10 per ton, and on account of the heavy

transportation charges they are unable to ship it. To overcome this they will erect a mill in the spring to treat the ore. The mill will be a custom one as well, as there are a number of dumps in the neighborhood that can be treated.

TELLER COUNTY—CRIPPLE CREEK

The Cripple Creek district enters upon the new year with bright prospects. A large amount of mining is being done, both by the companies and leasers. All is quiet in labor circles and the relations between the employer and the miner are cordial. The Mine Owners' Association is in control, and the card system is being enforced the same as it was a year ago. The drainage tunnel is being pushed steadily along. The milling situation is about the same as last year, with the exception of a little higher rate on some of the ores where there is no contract with the mill. There is a general tendency toward more reasonable royalties than in former years. A large amount of leasing is being done both by companies and by individuals in a small way.

Blue Bird—Connection has been made between the bottom level of this property and one of the Portland drifts, thus giving good air. The Blue Bird is under lease to the Humphreys-Thompson people, of Denver, and is said to be doing well. H. D. Thompson, of Cripple Creek, is in charge of the property.

El Paso Consolidated—A change has been made in the control of this company. Four of the old directors, S. S. Bernard, J. M. Beatty, George Bernard and E. J. Eaton have resigned and new directors have been put in. The present board consists of A. L. Burris, A. J. Styber, A. L. Doud, William Bainbridge, A. Kemple and J. H. Avery. Mr. Burris will be president and general manager and Mr. Bainbridge, who was formerly superintendent of the property, will be consulting engineer. For the past year there has been a struggle between the Bernard factions and that headed by Burris for the control of the company, and it was expected that there would be a fight at the annual meeting which occurs in March, but matters were precipitated by the calling of a special meeting. The property of the company is at present being operated under lease by a number of leasers. Mr. Burris lives in Colorado Springs.

Half Moon—The shaft-house on this property has been totally destroyed by fire. The property is controlled by the Stratton estate and is at present under lease to Charles Harrison and associates, of Cripple Creek. This property at one time produced a very large amount of ore.

Indiana

PIKE COUNTY

Solomon Deeble & Co., coal operators, of Carlisle, have leased several hundred acres of coal land north of Petersburg,

near the Evansville & Indianapolis railroad. The company will begin sinking a shaft at once. There are two veins of coal underlying this land—one a 4-ft. vein and the other a 7-ft. vein. Both will be worked, giving employment to several hundred men. The mines at Blackburn, Little Rodgers, Massey, Ayrshire, Fortwell and Winslow are operating from three to six days a week, and the railroad is now running from two to three extra coal trains a day. The Worley mines, owned by Arthur Jordon, of Indianapolis, which have been idle for two years, will be opened in a short time. The vein in the Killians mine has been found to be 13 ft. thick, and the coal is said to be of very good quality.

Louisiana

Petroleum production in Louisiana in December was 358,600 bbl. Shipments by rail were 203,128 bbl.; pipe line, 112,639; total, 315,767 bbl. During December 15 wells were completed, 12 being in oil and three dry. There were 44 wells drilling at the end of the month.

Michigan

COPPER

New Baltic Exploratory Company—Exploratory work has begun on the lands of this company which lie to the east of the Franklin, Jr., in view of opening the northern extension of the Baltic lode. Operations will be confined to trenching and drilling.

Superior—This company is accumulating rock preparatory to putting through another mill test. The first mill run consisting of about 900 tons yielded nearly 38 lb. of copper per ton. The rock is coming from the drifts of the four lower levels.

Atlantic—The crosscut from the 19th level of this company's shaft has struck the lode, but it has not yet been extended far enough to ascertain its conditions. The crosscut driven from the 15th level has encountered a lode at a distance of nearly 400 ft. from the shaft; its identity has not as yet been definitely decided and results of its further opening will be awaited with interest, as it may have a bearing on the future development of the property.

Calumet & Hecla—The first quarter of this company's large regrinding mill has gone into commission and is treating the tailings from the Calumet mill. The ultimate capacity of this plant will be about 10,000 tons daily, and it is to contain 48 Chilean mills and 200 Wildley tables. The Chilean mills with their quota of tables are arranged in multiples of six, each set driven by a 250-h.p. 2300-volt induction motor.

Michigan—Construction work on this-

company's stamp mill is going on in a limited way and the trestle approach to the building is being erected. Conditions are improving at depth in the mine. "A" shaft is sinking close to the 17th level and "B" shaft is down to the 14th level; the drift extended from this level is entering into a good copper-bearing formation after passing through practically barren ground for a considerable distance.

King Phillips—No. 1 shaft of this company has opened the lode by means of crosscuts to the 10th level, and the lower workings are yielding a good grade of rock which is being accumulated in a stock pile. No. 2 shaft is crosscutting to the lode at the sixth level. The recently installed electric hoisting equipment is working satisfactorily.

Il'yandot—Drifting continues on the amygdaloid lode that this company cut with its crosscut from the bottom of the exploratory shaft, and the copper showing is being maintained. This is the most important showing yet made on this property.

Tamarack—No. 1 shaft of this property is being put into shape to handle all the mine water from this tract, and a large concrete tank is being erected to store the water preparatory to its being hoisted.

Mass—This company has started to drive two crosscuts from "A" shaft to intersect the lode that was opened by a drill hole. One is being driven from the 15th level and the other from the 17th level.

Allouez—No. 2 shaft is down to the 13th level; the shaft is being turned so as to conform with the pitch of the formation which is expected to be cut within the next two levels.

Copper Range—This company will in all probability give up its option on the Globe tract upon its expiration in April. A shaft has been sunk to a depth of 1000 ft., and at that depth much prospecting has been done without finding anything of commercial value, or even any indications that would warrant further prospecting. One of the drills operating on the lands adjoining the old Atlantic property is down about 650 ft. and the other nearly 600 ft. Results from these holes are being awaited with interest as it is maintained that the northern lodes of the section extend across Portage lake and in proximity to these lands.

Winona—The directors will take action shortly regarding another assessment; this will probably be \$1 per share. The last assessment was \$2, of which \$1 was paid in the fall of 1907, and the balance in February, 1908. The need of additional funds at this time is due to the fact that the extensive development work which was carried on during 1908 and which cost between \$140,000 and \$150,000, has practically exhausted the working capital. The Winona discontinued rock shipments in November, 1907, at the time of the

break in the price of copper. It is proposed to resume shipments this spring. A much larger output is expected than heretofore. In 1907 the Winona shipped 102,100 tons of rock to the Adventure mill. The yield was 2,231,445 lb. of mass and mineral, or 1,285,863 lb. of refined copper, being 12.59 tons of refined copper per ton of rock shipped. By a more careful selection the management expects the yield can be brought up to 14 pounds or better without a material increase in cost.

Missouri

ZINC-LEAD DISTRICT

The natural-gas supply proved inadequate during the recent cold weather causing many of the mines and mills using gas to shut down.

Apache Maid—Barr, Gloniger & Walsh have let the contract for the erection of a 300-ton mill on their lease of this mine on the Troupe land south of Webb City.

Holdout—This company, composed of Chicago and Webb City parties, has been incorporated for \$32,000. Frank Forlow, of Webb City is attorney.

Knights—Several rich drill strikes on the Sampson land near Knights station bid fair to make this a producing camp.

Kathleen—This company has been incorporated with a capital stock of \$50,000, to operate at Belleville. W. F. Hilles, Dallas, Texas, J. Wise Brown, E. A. C. Elliott and F. B. Wilcox, of Joplin are the stockholders.

Transylvania Royalty Company—J. P. Newell, of Carthage, and New York parties have incorporated this company with \$100,000 of capital stock.

Montana

BUTTE DISTRICT

Amy Silversmith Mining Company—Several new leasers have lately begun work. The work is for the most part confined to the 300-ft. level.

Butte & Superior—The shaft has reached the 1400-ft. level where a large station is being cut and a pump installed. It is reported that more copper ore has been encountered on the 1200-ft. level where development work is now being carried on.

Daisy-Daly—The Colorado shaft has reached a depth of 1400 ft. Below the 900, the shaft has three compartments; above this point it has but two. Ground is now being stoped out, from the 900 up, which will make the entire shaft three compartments.

Butte-Montana—The company has shipped three 50-ton cars of ore from its Alec Scott mine to the Washoe smelter this week.

Butte Central Copper Company—This company has been recently organized

under the laws of Delaware. The company is capitalized at \$2,500,000, with 250,000 shares of the par value of \$10. When the old Butte Central & Boston Copper Corporation has been discharged from bankruptcy and its affairs untangled, the new company will assume control of the Ophir mine and begin operations. Freeman I. Davidson, largely interested in the old corporation, is instrumental in the formation of the new company.

Surprise Eagle Company—At a recent meeting of the directors it was decided to levy an assessment of one cent per share on all outstanding stock for the purpose of providing a working capital.

FERGUS COUNTY

Barnes-King—President Gillie has recently published his annual report to the stockholders. The report covers the period for the past 14 months, and contains reports of General Manager McGee and Treasurer Swinborne. It is stated that under the new management the monthly deficits of 1907 were changed into monthly profits in 1908, and that the cost of mining and development has been reduced from \$4.18 per ton to \$2.53. The treasurer's report states that on Nov. 30, 1908, there was a balance in the treasury of \$225,113.41, but that it will be some time before a dividend can be declared.

JEFFERSON COUNTY

Corbin Copper Company—At the first meeting of stockholders the following directors were elected: Stephen R. Dow, Alvin R. Bailey, Noah W. Jordan, George E. Larnard, David E. Dow and Richard M. Edwards. Stephen R. Dow is president and Alvin R. Bailey, secretary and treasurer.

Kelly Smelting and Refining Company—At a meeting of stockholders held in New York the name of the company was changed to the Alta Montana Copper Company. The company owns the Alta group near Corbin.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Goldfield Consolidated—The Clermont shaft, which will be the main working shaft of the company, is now 920 ft. deep. The Mohawk vein was intersected at 856 ft., 20 ft. lower than the bottom of the old Mohawk shaft. On passing through the hanging wall, quartz of a milling grade was entered, which showed for 60 ft. in the shaft; the barren spot which was then cut, still shows in the bottom of the shaft. Construction on the shaft house has al ready started, and the 200-h.p. hoist, which will be operated by compressed air, is daily expected.

Red Top—Drifts are being extended north and south on the lower level; an advance of 150 ft. was made last month.

Florence Goldfield—The new Florence mill commenced operations Jan. 9 with 10 of its 40 stamps dropping; the number will be gradually increased to the full capacity. In the Florence property large bodies of ore have been blocked out by the various leasers. This ore will be treated before much more development work is done. No new leases are being granted nor will extensions be given to any of the present leasers.

Florence Gem Lease—High grade ore was struck a few days ago; two wagon-loads of ore a day are being sent to the sampler.

Atlanta—Eight sets of lessees are working on this property; while small seams of good grade ore have been opened in several places, nothing of sufficient size to warrant shipping has been developed.

Goldfield C. O. D.—In a winze from the 250-ft. level 15 in. of high-grade ore was recently opened. Work is still progressing in the winze, and the drift on the 300-ft. level is being pushed to catch this oreshoot. The company has a large tonnage of milling ore developed.

Consolidated Red Top Lease—While the management will not give out definite figures, it is generally known that the face in the oreshoot found between the 225- and 300-ft. levels, is showing richer than ever before. The drift on the 300-ft. level is being extended south to catch the oreshoot on its downward pitch, and, as ore assaying \$30 per ton now shows in the breast, it should be close to the shoot.

ESMERALDA COUNTY—STIMLER

Cottonwood Mine—Returns from a 20-ton shipment from this property gave \$62 in gold and \$51 in silver per ton. In the bottom drift, where the dike was cut, the orebody is 40 ft. wide. The property is equipped with a 20-h.p. hoist. Considerable development work is being done.

NYE COUNTY—BULLFROG

Smith Brothers' Mill—It is reported that Smith Brothers have made arrangements which will enable them to resume operations on their custom mill at Beatty, and that work will be rushed from now on to completion. With the exception of the cyanide tanks, the material is now on the ground. This is a ten-stamp mill; the batteries were furnished by the Hendrie Bolthoff Company. The mill will be run by electric power obtained from the Nevada-Algonia Electric Power Company.

Shoshone—The returns as given by the State bullion-tax collector credit the Shoshone with a production of \$535,763 for the first nine months of 1908. The "glory hole" is nearly 150 ft. long by 100 ft. wide by 200 ft. deep at the west end; over 10,000 tons of ore are now broken in the glory hole. The ore goes through chutes to the 200-ft. level whence it is hoisted to surface.

Gold Bullfrog Mining and Milling Company—A 25-h.p. gasoline hoist has been installed on this property and sinking will be resumed; the shaft is now 150 ft. deep.

Mayflower—The buildings for the new five-stamp mill have been completed and are now ready for the machinery, nearly all of which is on the ground. A station has been cut at the 500-ft. level; water for the mill will be pumped from that level. There is sufficient ore on the surface to supply the mill for two months; this, together with ore blocked out on the 200-ft. and 300-ft. levels will supply the mill until lower levels are ready for production.

NYE COUNTY—SPRINGDALE

Newcomer Mill—The 50-ton custom mill being built by Scott Newcomer at Springdale is nearly completed and is expected to be in operation by the end of the month. Should the treatment, which consists of roasting before cyaniding, prove a success, the Pioneer mine will furnish the mill with all the ore that it can treat.

NYE COUNTY—BULLFROG

Bullfrog Mining Company—A 10-ton shipment to the Western Ore Purchasing Company from the Stewart & McVicar lease on Ladd mountain gave returns of \$86 per ton.

Pioneer—This property is still the center of attraction. The drift from the sub-winze shows 15 ft. of ore that assays more than \$100 per ton as it is broken.

NYE COUNTY—TONOPAH

Belmont—Extensive development work is being done on the 1100-ft. level, the deepest point at which ore has been found in Tonopah. In the raise from the 1100-ft. level the company is working on the largest body of ore yet developed in this mine. This is the same body of ore in which the big winze from the 1000-ft. level was sunk, and which was exposed on that level by a drift for a distance of 200 ft. Owing to the divergence of the two faults which terminate this oreshoot on the 1000-ft. level, it should be exposed for a distance of more than 400 ft. on the 1100-ft. level.

NYE COUNTY—MANHATTAN

Moore Lease No. 5—In a test at the Vieth mill 18 tons of ore from this lease on the Manhattan Earle property yielded 61 oz. of amalgam, which it is estimated will make an average of \$45 gold per ton of ore. The ore was all taken from the working shaft now 90 ft. deep. The company intends to install a gasoline hoist.

NYE COUNTY—ROUND MOUNTAIN

Jefferson Mine—Charles Kanraht, who recently sold this property to the McBeth

syndicate, of New York, is authority for the statement that there is now \$43,000 worth of machinery on the ground and that \$30,000 additional will have to be spent to properly equip the mill and mine.

HUMBOLDT COUNTY—SEVEN TROUGHS

Sandifer Lease—This lease recently broke out a fair sized body of high-grade ore on the 250-ft. level.

HUMBOLDT COUNTY—WINNEMUCCA

Intermountain Mine—Work is to be resumed on this property, which lies close to the town of Winnemucca. W. G. Adamson, superintendent of the company, states that the shaft, now 250 ft. deep, will be sunk to a depth of 400 ft., at which point it is expected to cut the Pride of the Mountain vein. This property was one of the early producers of the State and is credited with a production of more than \$400,000.

Golden Eagle Mine—This property started work last week with Hasal Power as manager. For the present the ore will be concentrated at the company's mill and the product shipped. Later the company will erect a cyanide plant. The property is about 30 miles west of Winnemucca, and three miles from the Western Pacific at the old camp of Central.

North Carolina

IREDELL COUNTY

A deposit of asbestos is being opened near Statesville by Charles Lambert, of Pittsburgh, Penn. The asbestos so far found is said to be of good quality.

Oklahoma

The production of petroleum in December is reported by the *Oil Investors' Journal* at 3,796,600 bbl.; deliveries, 3,112,018 bbl. Added to stocks, 684,542 bbl. Total stocks on Dec. 31 were 52,097,200 bbl., as estimated. During December 217 wells were completed, of which 271 were oil producers, 8 gas producers and 18 dry. There were 286 wells drilling at the end of the month.

OTTAWA COUNTY

Several drills are at work prospecting near Afton, and some strikes of zinc and lead ore are reported.

Oregon

LANE COUNTY

Much development work is being done in the Bohemia district, which lies partly in Lane and partly in Douglas county. This work is of a character that denotes permanency, as it consists of road building, the shipping in of machinery, tunnel work, etc. The miners of this camp have overcome the habit of doing only assessment work each year and are now expending all their available money on development work.

Vesuvius—The 10-stamp mill on this property near Bohemia postoffice is now running. The returns are said to be very satisfactory, but no details can be learned. Mr. Hand, who is manager of the Vesuvius mine, is also doing extensive work on the Oregon-Colorado and Riverside properties.

Combination Mines Company—This company was recently organized under the laws of Oregon, and has taken over the Combination mines owned by Clark Brothers. The officers of this company are R. H. Clark, of Milwaukee, Wis., president and treasurer; W. T. Clark, of Wenatchee, Wash., vice-president; J. W. Disch, of Milwaukee, Wis., secretary. The capital stock consists of 450,000 shares, par value \$1; 200,000 shares are held in the treasury. This company has a high-grade concentrating property and is now installing machinery with which to work it. The Eastern office is at Milwaukee.

Martin Creek Mining Company—Good ore carrying gold and silver is being mined at this property near the Combination mines.

Mayflower Mines—Considerable development work is being done; machinery for a 100-ton mill is on the ground. The recent heavy fall of snow has caused a suspension of surface work, but it will be resumed as soon as the snow is gone. W. P. Ely is manager.

Twin Rocks Company—At the annual meeting of this company, recently held at Cottage Grove, the following officers were elected: President, Lewis Hartley, Cottage Grove, Ore.; vice-president, Geo. B. Spitzer, Mt. Zion, Ill.; secretary-treasurer, W. B. Hartley, Cottage Grove, Ore. A block of 50,000 shares of stock was voted to be sold so as to raise additional money for development and machinery.

West Coast Mines Company—Several men are at work on this property and more will be put to work soon. It is the intention of the management to put the mill in working order and to commence dropping stamps as soon as enough ore is broken to assure a steady run for the 30 stamps.

Sweepstakes—A vein of solid quartz 16 ft. wide and rich in gold has been found at this property. S. J. Brund is owner.

Black Butte—This quicksilver mine about 12 miles south of Cottage Grove is now a paying proposition. For the last ten years money has been spent in development, and over four miles of drifts have been run to open up this large body of cinnabar ore. The furnace invented by Mr. Dennis, manager of the property, in successful operation and considerable refined quicksilver is being shipped. This property is owned by New York men.

Pennsylvania

ANTHRACITE COAL

Penn Coal Company—The district court has issued a peremptory order directing this company to take measures at once to extinguish the fire which has been burning in its colliery at Carbondale for more than a year. The order was issued in a suit brought by residents of the town, who complained of the gases escaping from the mine, and also of the danger of surface caves, as the coal below was burned out. The company has given notice of an appeal to the Supreme Court.

South Dakota

LAWRENCE COUNTY

American Eagle—Before the mill can be operated a water supply must be secured. The company will in the spring run a crosscut from rimrock to rimrock, build concrete dams and pump the water to the mill. The mine will be developed all winter.

Branch Mint Operating Company—Manager Hecht, of New York, is dropping 60 stamps daily in the mill which is running on the old Richmond dump.

Homestake—Preparations are being made to erect a power plant on Spearfish creek that will use 100 cu. ft. of water per second. The plant will require 1½ years and \$1,000,000 to build. Advertising the water right and ground has been commenced by the company.

PENNINGTON COUNTY

Fairview—Jerry Harrington is opening up this claim near Mystic, and has found a ledge of free-milling gold ore, 2 ft. in width, which will be treated in the old Cuttsark stamp mill that has been moved over to the property.

Forest City—This property, formerly the Clara Belle, at Oreville, is about to resume under the management of the Cleveland interests. A new shaft will probably be sunk.

Texas

The field reports from the southeast districts of Texas show 57 wells completed, 44 being oil producers and 13 dry holes. There were 71 wells under the drill on Dec. 31. The production of petroleum in December was 949,730 bbl. Shipments by rail were 618,722 bbl.; by sea, 147,512; total, 766,234 bbl. It is estimated that 150,000 bbl. were consumed in refineries and 75,000 bbl. in field operations.

Utah

SALT LAKE COUNTY—BINGHAM

Cash Copper—The seventh steam shovel is now in operation; there is still another shovel being assembled. Five steam shovels are stripping overburden and two working on ore. The mine is shipping,

as nearly as the railroad facilities will permit, the full tonnage that can be handled by the mill.

Utah-Bingham—Since last fall the mine has been equipped with machinery, air drills, etc. The main vein has been developed for 900 ft. along its strike by three adits and raises connecting them. Considerable ore is developed, but owing to the condition of the roads shipping has been stopped until next spring.

Boston Consolidated—A serious cave has occurred in the Ben Hur adit.

TOOELE COUNTY

Shipments—During the week ending Jan. 1, the Sioux Consolidated shipped 11 carloads: Iron Blossom, 3; Eureka Hill, 3; May Day, 2; May Day concentrates, 2; Centennial Eureka, 2; Yankee, 2; Uncle Sam, 4; Gemini, 3; Eagle & Blue Pell, 1; Bullion Beck, 2; Colorado, 33; Dragon Iron, 10; Black Jack, 1; Swansea, 5; Lower Mammoth, 2; Brooklyn, 3 carloads. All these were 30-ton cars except those from the Colorado, Dragon Iron and Swansea mines, which were 20-ton cars. Six thousand five hundred bars of bullion were shipped from the smelter during the past week, bringing the total for the month of December up to 29,484 bars.

Shipments from the Tintic mines for the week ending Jan. 8 were as follows: Sioux Consolidated, 12 cars; Iron Blossom, 3; Consolidated Eureka, 4; Eureka Hill (leases), 6; Uncle Sam, 8; May Day, 4; Yankee, 3; Bullion Beck, 2; Ajax, 2; Colorado, 47; Dragon Iron, 23; Black Jack, 7; Brooklyn, 1; total, 162 cars. All these were 30-ton cars except the 20-ton cars from the Colorado, Dragon Iron, and Black Jack mines.

Lower Mammoth—About 300 ft. of the main shaft has been retimbered; it will require 90 days to complete the work to the 1200-ft. level. The assessment period will probably continue until fall. The officers of the company are John Dern, president; A. J. Stewart, vice-president; W. S. McCormick, treasurer. The other directors are D. L. Wertheimer, E. C. Coffin, A. T. Moon and M. P. Bruffet. A. Reeves is secretary.

Little Chief—New machinery has been installed. The placing of guides for the counterbalance for the new hoist will require another week, as 1400 ft. of guides must be put in place. Drifting will then begin on the 1000-ft. and 1400-ft. levels.

Honorine Extension—At this mine at Stockton a blind lode has been found in a drift driven east on the Honorine vein from the Honorine company's old 600-ft. level tunnel. This is 600 ft. below the Honorine Extension tunnel. The orebody has been drifted on for 20 ft. and the ore is still good in the face. The width of the find is unknown, but the whole drift is in ore. The ore assays 25 per cent. lead, 14 oz. silver and \$6.00 gold per ton. The

cross-fissure at which this ore is found was barren in the level above; the next cross-fissure is 125 ft. distant. As the find is in ground thought by many to be unmineralized, it promises to give new life to Stockton.

West Virginia

FAYETTE COUNTY

Nuttallburg Collieries Company—This new company, recently organized with \$200,000 capital stock, has taken over the property of the Nuttallburg Coal and Coke Company, comprising 4160 acres of coal land, of which about 3000 acres are undeveloped; arrangements have been made for making several additional openings, and it is expected to double the present output. Dr. H. L. Kirkpatrick, Macdonald, W. Va., is president; John M. Alderson, Alderson, W. Va., vice-president; Angus McDonald, Charleston, W. Va., secretary; Lee Long, Charleston, W. Va., general manager and treasurer.

Wyoming

The principal producer of copper in this State continued to be the Penn-Wyoming Copper Company, of the Encampment district. During 1908 the smelter of this company operated only 119 days, producing 2,384,356 lb. of copper from ore yielding 125.6 lb. per ton. The company is now operating a new and enlarged smelter.

Canada

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ended Jan. 9 were: Buffalo, 44,020 lb.; Coniagas, 35,630; Cobalt Central, 40,000; Chambers-Ferland, 80,000; La Rose, 193,560; McKinley-Darragh, 44,020; Nipissing, 127,500; Nancy Helen, 40,000; Temiskaming & Hudson Bay, 80,000; Muggley Concentrator, 72,900; total, 777,850 pounds.

Crown Reserve, Cobalt—The annual meeting held at Montreal Jan. 12 was attended by about 200 shareholders. The statement submitted showed that after payment of dividend due Jan. 15, amounting to \$283,210, the company would carry forward a surplus of \$317,117. During the year ore was taken out to the value of \$910,350. President John Carson estimated the value of the output for 1909 at \$1,200,000 which, allowing \$200,000 for operating expenses, would leave \$1,000,000 available for dividends. The intention of the directors is to pay dividends quarterly at the rate of 24 per cent. per annum and such bonuses as may be justified by earnings.

Hargraves—The main shaft of this mine, Cobalt, is going down at the rate of 2 ft. per day, and has reached a depth of 90 ft. A crosscut will be run to tap the Jacobs vein at depth and will be con-

tinued 100 ft. beyond it to strike a strong parallel vein.

Nipissing—During 1908 this mine produced 7,062,527 lb. of ore yielding 2,897,446 oz. silver of a net value, f.o.b. Cobalt, of \$1,384,447. The ore averaged 19c. per pound. Sinking continues at the Fourth of July shaft, which is now down 121 ft. At the Meyer vein the west drift has been prepared for stopping. The vein shows a width of from 2 to 8 in. averaging 3500 oz. silver to the ton, over a distance of 40 ft. At the Kendall shaft drifting is proceeding both ways on the new cross-vein. The north vein, which averaged 4 in. wide and assayed 2000 oz., has faulted. On the south end of the vein it has split into 3 stringers each about 1 in. wide and running from 1500 to 2500 oz. silver to the ton. The middle vein is being followed up.

White Silver—At this mine, on the Temagami reserve, a shaft is down 30 ft. on a vein carrying high silver contents. About \$50,000 has been spent on machinery and development and a quantity of ore is awaiting shipment.

ONTARIO—KENORA DIVISION

Kenora Prospectors' and Mine-Owners' Association—The first general meeting of this association was held at Kenora, Jan. 12. The following officers were elected: Honorary president, Capt. H. A. C. Machin; president Major J. E. P. Vereker; vice-president, Thomas Walsh; executive committee, Mayor Rideout, John Nash, H. D. Alston, J. Beck, W. G. Cameron, J. A. Whitney and A. Stevenson. Committees were appointed to draft resolutions for presentation to the provincial government asking that the timber on lands patented by miners should become the property of the patentee, and that State aid should be given for the development of the mining resources of the district.

Mexico

CHIHUAHUA

Batopilas—A shipment of 200 bars of silver bullion was made from this old property in the western part of the State early in January. Production is increasing owing to recent important discoveries of high-grade ore.

Parral Output—The production of the Parral camp for the month of November was 34,485 tons, and for the month of December, 28,889 tons. For the last week of December it was 7815 tons, and for the first week of January, 7840 tons.

Las Cuadras—These old properties in the Santa Barbara camp are again active under the direction of Charles M. Dobson. Shipments are in progress.

Sau Antander—This mine in the Santa Eulalia camp is now outputting at the rate of one carload a day; the ore goes to the Chihuahua plant of the American

Smelting and Refining Company. C. O. Calahan is the owner.

Rio Tinto Copper Company—This company's new 300-ton copper smelter in the Terrazas camp is scheduled for blowing in not later than Jan. 20. The company is purchasing out-of-the-district ores, especially copper sulphide and silicious ores.

Minas Tecoteles y Anexas—The mill at this Santa Barbara property operated by the American Smelters Securities Company, is treating approximately 800 tons of ore daily. Since its remodeling the plant is operating more efficiently. The average value of the ores milled is given as 20 grams silver, 3 grams gold, 7 per cent. lead, and 8 per cent. zinc. Wet concentration is practiced. It is reported that the company has in view the early erection of a zinc plant for the treatment of a large tonnage of accumulated middlings and tailings. W. M. Drury is the manager in charge.

Palmor Mining Company—This company, operating in the Parral camp, is said to have lately opened up ore of minable grade, and is contemplating the installation of heavier hoisting machinery.

El Tesoro Mining Company—This St. Louis company is successfully operating several properties in this State, as well as in Sinaloa. Its more important mines are in the vicinity of Guadalupe y Calvo and Choix. W. C. Harlan and A. W. Warwick are directing operations. The mill at El Tesoro mine is in operation.

Concheño—Corrigan, McKinney & Co., of Cleveland, Ohio, have taken back this mine as the Greene Gold-Silver Company forfeited over a year ago upon its second payment after having paid \$500,000 on the purchase price of \$1,250,000.

JALISCO

Cinco Minas—At this mine in the Hostotipaquillo district which is being developed by the Marcus Daly estate under the direction of H. E. Crawford, a new body of ore has been found. It now appears certain that the Daly estate will complete the purchase of this property.

New Railroads—Considerable railroad building is going on in western Mexico. The Southern Pacific is building from Guaymas to Guadalajara as fast as it can. It is understood that the intention is finally to connect this road with the Pan-American at San Geronimo on the Isthmus of Tehuantepec. The Pan-American is now completed as far as the Guatamala border. The Mexican Central has its branch from Guadalajara to Manzanillo on the Pacific in operation.

SONORA

Greene-Cananea—Six furnaces are now in operation. The production of copper for the past 17 months was \$8,180,856 lb. The company employs 4000 men.

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, Jan. 20—In the Seaboard bituminous-coal trade dullness prevails as it has for some time past. A revival in the demand for steam coal was expected in some quarters in January, but these prophets are now postponing the good times for 60 days longer. The fact is that manufacturers are not buying with any degree of freedom in the East, and seem to be satisfied with enough to meet their immediate needs. Talk of season contracts is heard, but nobody seems disposed to start the business, and little or nothing will be done on this line for a month or more to come.

The anthracite trade is quiet. Some of the large companies are cutting off one or two days' work a week from the working time at the collieries; others are running full time, but not pushing work. Shipments continue and it is still evident that a good deal of coal is being stored.

In the West there are more signs of revival, though business in steam coal continues rather slow. There has been cold weather throughout the week, however, and from most consuming centers a better demand for household coal is reported. In Indiana mining time has been increased and many mines are running four days per week, with a few full time. In Illinois short time seems to be the rule. There is rather less complaint heard at the distributing centers of overshipments, notwithstanding the usual tendency of operators to load up the sidings at the large cities.

Coke business shows more hopeful signs than any other branch of the trade. Production in the Connellsville region is increasing from week to week, and the Pennsylvania Railroad reports larger shipments of coke than for a year past.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to Jan. 11, 1908, and Jan. 9, 1909, in short tons:

	1908.	1909.	Change.
Anthracite.....	123,320	63,216	D. 60,104
Bituminous.....	985,266	784,448	D. 200,818
Coke.....	193,973	253,625	I. 59,652
Total.....	1,302,559	1,101,290	D. 201,270

The total tonnages give daily averages of 118,415 tons in 1908, and 122,365 tons this year.

Bituminous coal and coke shipments, Pennsylvania and West Virginia, 11 months ended Nov. 30, short tons:

	Coal.	Coke.	Total.
Balt. & Ohio.....	20,535,661	2,771,487	23,307,148
Buff. & Roch. & Pitts.	4,982,888	300,353	5,283,241
Buff. & Susquehanna	1,059,525	185,847	1,245,372
Penn. Lines, N. Y. C.	6,170,610	65,414	6,236,024
Pitts. & L. Erie.....	7,502,114	2,702,832	10,204,946
Norfolk & Western.	10,194,955	1,752,261	11,947,216
Total.....	50,445,753	7,778,194	58,223,947
Total, 1907.....	61,705,402	13,092,432	74,887,834

The total decrease this year was 16,663,887 tons, or 22.3 per cent. In addition to the above, the Baltimore & Ohio carried 947,612 tons anthracite in 1907, and 719,681 in 1908; decrease, 221,931 tons.

Coal tonnage of railroads in Ohio Coal Traffic Association, 11 months ended Nov. 30, short tons:

	1907.	1908.	Change.
Hocking Valley.....	3,826,978	3,033,023	D. 793,955
Toledo & Ohio Cent.	1,588,748	1,473,228	D. 215,520
Baltimore & Ohio.....	2,100,377	1,319,540	D. 780,838
Wheeling & L. Erie.	3,213,825	2,439,773	D. 774,052
Cleve., Lorain & Wb.	2,736,986	2,217,064	D. 519,922
Zanesville & Western	1,455,471	1,180,104	D. 275,367
Toledo Div., Pan. Co.	2,084,111	1,410,129	D. 673,983
L. Erie, Alliance & Wb.	1,149,587	986,756	D. 162,831
Marietta, Col. & Cleve.	34,752	50,791	I. 16,039
Total.....	18,287,835	14,164,416	D. 4,123,419

The total decrease shown in 1908 was 22.5 per cent.

Coastwise shipments of coal from chief Atlantic ports, 11 months ended Nov. 30, long tons:

	Anthracite.	Bitum.	Total.	Per cent.
New York.....	13,698,715	9,244,744	22,943,459	62.6
Philadelphia.....	1,351,031	4,254,943	5,605,974	16.9
Baltimore.....	228,206	3,337,890	3,566,096	9.7
Newport News.....		2,480,609	2,480,609	6.8
Norfolk.....		1,471,884	1,471,884	4.0
Total.....	15,877,952	20,789,970	36,667,922	100.0
Total, 1907.....	17,747,371	22,524,791	40,272,162	

Total decrease in 1908 was 3,604,240 tons, or 8.9 per cent. New York includes all the New York harbor shipping points.

Shipments of coal by water from Seattle and Tacoma, Wash., 11 months ended Nov. 30, were 657,334 tons in 1907, and 451,784 in 1908; a decrease of 205,550 tons. These shipments are chiefly to California and Alaska ports.

Coal receipts at St. Louis 11 months ended Nov. 30 were 7,413,151 short tons in 1907, and 6,268,039 in 1908; decrease, 1,145,112 tons.

The coal shipments reported by the Southwestern Interstate Coal Operators' Association for the year 1908 are, in short tons:

Missouri.....	2,416,201
Kansas.....	5,178,934
Arkansas.....	1,887,328
Oklahoma.....	2,666,808
Total.....	12,109,271

The total in 1907 was 14,656,338 tons, showing a decrease in 1908 of 2,487,068 tons, or 17 per cent.

New York

ANTHRACITE

Jan. 20—The hard-coal market must still be reported very dull. The sharp cold weather which came with the opening of this week has not lasted long enough to have any marked influence on the trade. Domestic sizes are selling slowly. In steam sizes there is a little more activity, but nothing beyond the usual demand. All sizes are in good supply.

Prices are unchanged. The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS

The soft-coal market is dull, no new demand for steam coal having developed. The far East is taking no coal and along the Sound deliveries are light with no new orders, or at least very few. New York harbor business is extremely dull and prices are nominal at \$2.45@2.65 New York harbor for good grade Clearfield. Off grades are offered lower. All-rail business is slow and the snow and ice storm of this week has interfered a little with transportation.

In the Coastwise trade there is nothing doing. Freight rates are nominal at about the same as last week. The stormy weather has interfered with this trade and vessels are not anxious to clear just now.

Birmingham

Jan. 18—There is need for more coal, and the output has been steadily improving since the first of the year. The railroads are handling coal promptly. In addition to the increasing needs of some of the larger consumers, the coke production is being pushed. The coke supplies are now somewhat better than the demand, but several furnaces are to be blown in soon, while foundries and machine shops are starting up that will require all the coke that can be furnished.

Chicago

Jan. 18—Owing to cold weather the market for domestic coals remains good, and steam coals show no weakening. Western coal has moved steadily as fast as it has been received, leaving little ground for complaint about demurrage

charges, although on some consignments these charges have cut prices to the extent of 10 or 25c. on Illinois lump. Fine coals are firmer in tone, and the whole market shows improvement for products of Western mines. Eastern coals in general share in the improvement, but smokeless continues depressed because of large receipts that force low prices.

Illinois and Indiana coals bring \$2@2.65 for lump and egg, \$1.65@1.75 for run-of-mine, and \$1.30@1.65 for screenings. On smokeless lump and egg quotations run \$3.15@3.65 for Pocahontas and New River lump and egg, and \$2.75@3.15 on run-of-mine, with lower grade smokeless \$3.05@3.55 for lump and \$2.75@2.95 for run-of-mine. Hocking holds up well to the \$3.15 list price. Youghioheny is quiet at \$3.15 for 34-in. gas. Pittsburg No. 8 is in somewhat large supply and brings \$2.70@2.85 per ton.

Anthracite is in good demand in city and country, with practically no shading of prices for independent coal, and with no trouble about supplies.

Cleveland

Jan. 19.—Receipts at Cleveland by rail in December included 87,411 tons anthracite, 266,326 tons bituminous coal and 76,173 tons coke. Practically none of the anthracite or coke was forwarded, but during the first days of the month 49,972 tons of bituminous coal were reshipped by Lake.

Steam trade is quiet, and the recent demand for slack seems now to be about over. Cold weather has started up a better demand for domestic coals. The market as a whole, however, must be called quiet, almost dull.

Indianapolis

Jan. 18.—Here and there are signs of improvement in the coal trade. This is partly due to the coming of severe cold weather, starting domestic demand up with a rush. In Sullivan county, for instance, news comes of the adoption of a five-day weekly schedule for a number of mines and the lengthening of the schedules in others. The mines are now in better condition, financially, than any time since the spring of 1908. Mines that have been running only one and two days in the week are now running three and four days. A few are operating six days.

Pittsburg

Jan. 10.—The rivers reached a coal-boat stage on Saturday and Sunday and nearly 2,000,000 bu. were shipped to St. Louis and New Orleans. There is still a large stage but little coal is going out. A good rise is expected later in the week, when efforts will be made to get out all the coal loaded in the pools and harbors. Many empty barges arrived and were immedi-

ately sent to the mine tipples in the upper pools of the Monongahela river. As a result all the idle mines along the river resumed operations yesterday. The railroad mines are being operated at around 60 per cent. The demand is not strong, but prices remain firm on the basis of \$1.15 a ton for mine-run coal at mine. There is some slight shading of this rate by small independent concerns, but the large operators are determined to maintain the price. A start has been made at the Marianna mine of the Pittsburg-Buffalo Company where the serious explosion occurred last month. About 50 men are working in each shift, and it is proposed to increase the number gradually.

Cornellsville Coke—A decided slump in spot furnace coke prices is noted and sales have been made as low as \$1.50; it is reported that one sale was at \$1.35 a ton at ovens. Large producers are holding firmly for \$1.75 for spot and \$1.90@2.10 on contract for the first half. Foundry coke has not dropped materially and for spot shipment it will be difficult to do less than \$2.10. On contract, quotations continue at \$2.25@2.40 a ton at ovens. The *Courier* gives the production at 265,158 tons. Shipments were 9179 cars as follows: To Pittsburg district, 3406; to points west of Pittsburg, 5101; to points east of Cornellsville, 672 cars.

Foreign Coal Trade

German Coal Production—Coal production of the German Empire, 11 months ended Nov. 30, metric tons:

	1907.	1908.	Changes.
Coal	131,393,100	136,729,987	I. 5,336,887
Brown coal	56,853,293	60,934,889	I. 4,081,596
Total mined	188,246,393	197,664,876	I. 9,418,483
Coke made	20,925,165	19,537,382	D. 1,387,783
Briquets made	15,943,430	16,813,871	I. 1,770,441

Of the briquets made in 1908 there were 13,101,439 tons, or 77.9 per cent. of the total, made from brown coal, or lignite.

German Coal Trade—Imports and exports of fuel in Germany, 11 months ended Nov. 30, metric tons:

	1907.	1908.	Changes.
Imports:			
Coal	12,549,210	10,745,167	D. 1,804,043
Brown coal	8,163,446	7,929,938	D. 242,508
Total coal	20,712,656	18,666,105	D. 2,046,551
Coke	638,739	518,588	D. 120,151
Briquets	175,000	172,923	I. 1,893
Exports:			
Coal	18,115,184	19,192,539	I. 1,077,355
Brown coal	20,039	25,449	I. 5,410
Total coal	18,135,223	19,217,988	I. 1,082,765
Coke	3,471,671	3,815,691	D. 155,980
Briquets	1,126,539	1,381,559	I. 255,020

The coke exports in 1908 include 125,075 tons to the United States.

Welsh Coal Prices—Messrs. Hull, Blyth & Co. London and Cardiff, report current prices of coal as follows, on Jan. 8: Best Welsh steam, \$3.48; second, \$3.30; third, \$3.24; dry coals, \$3.60; best Marmor-mouth-shire, \$3.18; seconds, \$3.06; best small steam, \$2.04; seconds, \$1.74. All per long ton, for shipping port.

Iron Trade Review

New York, Jan. 20—The iron and steel markets in general, while they show no signs of the widespread activity which was predicted for January, are nevertheless improving a little. The advance, however, is very slow.

In pig iron the inquiry is better and orders are reported to be coming in. They are mostly small, however, indicating that the foundry people are still satisfied to supply their immediate needs and have not in sight as yet business enough to warrant them in placing large contracts. Forge iron is dull, and basic pig is only in moderate demand. Prices of pig generally are rather uncertain. Some furnaces have talked of advances, but find that the only result is to check orders.

In finished material—with the exception of structural steel—business is also generally on a small scale. Orders do not come in with any degree of freedom except for moderate quantities. The railroads are still out of the market so far as rails are concerned, though they are placing some orders for bridge work. In structural steel more is doing than in any other branch. In the Eastern cities orders for buildings are being placed, some of them of fair size. The whole makes a very good aggregate tonnage. It is observed that the large fabricating companies in New York and elsewhere are taking contracts which would seem to imply the purchase of steel from the mills at 1.25 or 1.30c, if a profit is to be figured out. This is from 0.40 to 0.50c. below the tidewater prices of beams and other structural material.

Shipments of iron ore from the Lake Erie docks to furnaces are still reported as slow. The docks are generally congested, and unless there is a very considerable movement between now and May 1 they will not be ready to receive shipments from the upper Lake ports.

Baltimore

Jan. 19.—The only exports noted for the week, besides copper, were 536,250 lb. scrap tin to Rotterdam.

Birmingham

Jan. 18.—While the activity that is desired has not yet asserted itself, Southern pig-iron producers are selling iron right along and the aggregate is showing up well. One or two orders of some proportion have been booked in the Birmingham district recently, while numerous small orders, early delivery, are noted. The quotations hold strong at \$13 per ton, No. 2 foundry. The furnace companies which have been sounding a 50c. advance do not report any business transacted. Some of the larger melters have again started an inquiry as to iron.

There is a large consumption of iron right in the Birmingham district. The

big steel plant of the Tennessee company is now on full in every department. The Bessemer rolling mill, belonging to the same concern is turning out finished iron and steel again. The cast-iron pipe concerns are all active, while foundries and machine shops show further improvement.

By TELEGRAPH

Birmingham, Jan. 20—The Sloss-Sheffield Company sold today 20,000 tons of foundry iron to a leading cast-iron pipe plant on a basis of \$13 per ton, first-half delivery. It is rumored here that the Alabama Consolidated Coal and Iron Company has bought the large plant of the Dimmick Pipe Company.

Chicago

Jan. 18—There is little activity in iron of any sort. Users of pig iron continue to buy in small quantities and for needs of the immediate future chiefly. Both buyers and sellers seem to have come to the conclusion to abandon contracts reaching any considerable distance ahead for deliveries, and inquiries are neither numerous nor for large tonnage. Despite this quietness the market has no indications of weakening, consumption being apparently well matched by production.

For the small lots that are being sold \$13@13.50 Birmingham (\$17.35@17.85 Chicago) for Southern and \$17.50@18 for Northern are standard prices. Any considerable order could probably shade these quotations. Business is gradually resuming its normal tone following the holiday season, and the changes of the first of the year, and in sales of iron and steel products there are signs of increasing strength. Coke is somewhat stronger, with the best Connellsville in good demand at \$1.00@1.05 Chicago.

Philadelphia

Jan. 20—Local consumers are making no effort to cover second quarter requirements for pig iron. There is no increase in shop or foundry work at present. Eastern furnace interests are not soliciting orders and a few makers have refused to sell at less than December prices. Inquiries have fallen off, except in a few instances for basic pig. Buyers claim that pig iron has not touched bottom and refer to the drop in Southern pig quotations during the past few days. At present an accumulation is in progress but makers express confidence in a heavy compensating demand which they think is liable to break out any time. Pipe works are ready to extend their orders but are insisting on lower prices. Some central Pennsylvania furnaces are again making very low offers for early delivery. Some special brands of Lehigh Valley iron are advanced 50¢ nominally, but no sales have been reported yet.

Steel Billets—Contracts of some magnitude have been closed for bills of

days delivery. Prices continue on the basis of former contracts.

Bars—All bar mills are doing a little more business and there is a gradual return to normal conditions. A few good sized orders have been placed this week but at a shading from current prices.

Scrap—The sales of scrap have been unimportant. Foundries are buying a little. Heavy melting steel scrap is pretty well cleaned up. Consumers are fairly well supplied. Prices are weak. Dealers are on the war path for heavy scrap to hold.

Pittsburg

Jan. 19—There has been no material improvement in the iron and steel trade. Tinsplate leads the finished lines and production is being increased. The American Sheet and Tin Plate Company has started its American works, a 28-mill tinsplate plant at Elwood, Ind., and last week was operating 160 mills, or about 75 per cent. of capacity. This was increased yesterday when several more mills at different plants were put on the active list. Most of the independent tinsplate mills are running practically to capacity. When the spring trade opens it is certain production will be about normal. The same may be said of the wire trade. At present the American Steel and Wire Company is operating at around 80 per cent. of capacity and is booking many small orders. The Carnegie Steel Company yesterday started its Edgar Thomson rail plant in full, as in addition to receiving specifications on the Pennsylvania railroad order it has booked some foreign business. It is figured that the railroads will place orders for fully 3,000,000 tons, but of this there is no certainty. The structural steel trade continues dull, but there are some important contracts in sight which are being delayed on account of the talk of a probable reduction in prices. Every consumer that enters the market is determined to get the lowest possible price and usually succeeds, the shading, however, being done entirely by independent mills.

Pig Iron—A number of important transactions in different grades of pig iron have been closed within the past two weeks, but for certain reasons the buyers insisted that no publicity be given to the contracts. One concern in the past 10 days sold over 10,000 tons of iron of various grades and at different prices. Another sold several lots of malleable bessemer, which is apparently the strongest grade. One lot calls for 1200 tons and is for early delivery and the price was \$15.75. This price could not be depended on for second-quarter delivery. A sale of 600 tons of No. 2 foundry for prompt delivery at \$15.50 was made yesterday and another lot is under negotiation to go at a lower price. Basic iron is as strong as at the opening

of the year, when \$15.75 was named for first quarter, as a sale of several hundred tons was made within the past few days at \$15.50. It is said that this price cannot be shaded. Standard bessemer is weak. The effort to hold first-half iron at \$17 failed and now \$10.50 is the quotation made by large producers. However, a sale of 600 tons was closed last week at \$16.40. Gray forge is not in demand and is quoted nominally at \$14.50. All prices are f.o.b. Valley furnaces.

Steel—In the crude-steel market most of the business is on old contracts. The price of \$25, Pittsburg, is being firmly held for both bessemer and open-hearth billets. The announced price on plates continues at 1.00¢, but there is still considerable shading. Merchant-steel bars remain firm at 1.40¢.

Sheets—The sheet market shows improvement and production is being increased. Prices are firm, black sheets remaining at 2.50¢, and galvanized at 3.55¢, for No. 28 gage.

Ferro-Manganese—There is no demand, but prices are firm at \$46@46.50, Pittsburg.

Foreign Iron

Scotch Iron Production—The Scottish Ironmasters' Association has issued the following statement for the full years given, in long tons:

	1907.	1908.	Changes.
Stocks, Jan. 1, ...	90,548	96,043	L. 5,495
Make of pig, ...	1,403,447	1,230,191	D. 173,256
Total, ...	1,493,995	1,326,234	D. 167,761
Consumption, ...	997,692	827,627	D. 170,065
Exports, ...	400,260	312,662	D. 87,598
Total used, ...	1,397,952	1,140,289	D. 257,663
Stocks, Dec. 31, ...	96,043	186,045	L. 90,002

Of the exports in 1908, there were 142,783 tons to foreign countries and 160,732 to England and Wales.

Metal Market

New York, Jan. 20—The metal markets generally have been quiet, and no active revival of business is manifest as yet.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold			
Dec. 1908..	\$ 7,358,707	\$ 5,122,638	Exp. \$ 2,236,169

Dec. 1908..	4,726,299	4,392,290	Exp. 334,009
" 1907..	4,413,698	4,222,636	" 191,062
Year 1908..	51,837,671	42,195,866	Exp. 9,641,805
" 1907..	61,625,866	45,912,360	Exp. 15,713,506

Exports from the port of New York, week ended Jan. 18: Gold, \$5,930,000, chiefly to France; silver, \$1,010,000, chiefly to London. Imports: Gold, \$237,520; silver, \$169,014, from the West Indies, Mexico and South America.

Foreign commerce of the United States, year ended Dec. 31, reported by Bureau of Statistics, Department of Commerce and Labor:

Merchandise:	1907.	1908.
Exports.....	\$1,923,426,205	\$1,753,307,931
Imports.....	1,423,169,820	1,116,402,243
Excess, exports.....	\$ 500,256,385	\$ 636,905,688
Add excess of exports, silver.....		9,640,705
Add excess of exports, gold.....		30,968,357
Total export balance.....		\$ 677,515,750

The gold and silver movement in detail is shown in the table at the head of this column.

Gold—The price of gold in the open market in London fell off early in the week, but recovered later, 77s. 10½d. per oz. being paid for bar gold and 76s. 5½d. for American eagles. The Bank of France took most of the gold arriving from the Transvaal; but a total of \$3,100,000 was shipped to Argentina. A shipment of \$500,000 was also made to Argentina from New York.

Platinum—Prices still hold at \$23.50@24.50 for refined ingot, \$26.25 for hard and \$20@21 for scrap, depending upon the quality. The refiners seem to be waiting for something to turn up. They are evidently uneasy as to what may happen in the future, and are inclined to push prices as high as they possibly can, with little buying in sight just now. Our last report from St. Petersburg is also to the effect that dealers there are holding back in expectation of higher prices. This appears to be over-optimistic, in view of the fact that there is not at present enough buying to keep the market stiff. In some well-informed quarters it is thought likely that the price will decline before making any further advance.

Silver—Silver advanced to 24½d. in London on Jan. 18 on active buying for the Indian bazaars, but closes at 23 15/16d. with a lower tendency. Selling by China banks caused the fall, and the market is quoted dull at the decline.

SILVER AND STERLING EXCHANGE.

Jan.	14	15	16	18	19	20
New York.....	52½	52½	52½	52½	52½	52
London.....	24	24½	24½	24½	24½	28½
Sterling Ex.,	4.8745	4.8740	4.8740	4.8750	4.8740	4.8740

New York quotations, cents per ounce troy, fine silver; London, pence per ounce sterling silver, 6.925 fine.

Shipments of silver from London to the East, year to Jan. 7, reported by Messrs. Pixley & Ahell, London:

	1908.	1909.	Changes.
India.....	£ 207,500	£ 66,110	D. £ 141,390
China.....	61,000		D. 61,000
Straits.....			
Total.....	£ 268,500	£ 66,110	D. £ 202,390

Receipts for the week were £4000 from Chile and £170,000 from New York; £174,000 in all.

Copper, Tin, Lead and Zinc

	Copper.			Tin.		Lead.		Spelter.	
	Jan.	Lake, Cts. per lb.	Electrolytic, Cts. per lb.	London, £ per ton.	Cts. per lb.	Cts. per lb.	Cts. per lb.	New York, Cts. per lb.	St. Louis, Cts. per lb.
14	14½	13½	61½	28½	4.15	5.12	4.97		
14	14½	13½	61½	28½	4.20	5.17	5.02		
16	14½	13½	61½	27½	4.15	5.12	4.97		
16	14½	13½	61½	27½	4.20	5.17	5.02		
18	14½	13½	61½	27½	4.15	5.12	4.97		
18	14½	13½	61½	27½	4.20	5.17	5.02		
19	14	13½	60½	27½	4.15	5.12	4.97		
19	14	13½	60½	27½	4.20	5.17	5.02		
20	14	13½	60½	28	4.15	5.12	4.97		
20	14½	13½	60½	28	4.20	5.17	5.00		

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—Liquidation in the London market of some of the large speculative accounts, many of them originating from this side, to which we have previously referred, caused a break in the market for Standard. It has all along been feared that something of this kind would happen, and the situation is now clearer because of the liquidation of these accounts, which appears to have been inspired by the reports of large stocks of refined copper accumulated in this country, although some of these reports are greatly exaggerated. The lower prices established at London were immediately reflected in the quotations at which electrolytic copper was offered to domestic consumers. Though concessions have been made from day to day, such business as has been forthcoming either from Europe or from the home trade, has been only of a retail character. The market closes very unsettled at 14@14½c. for Lake copper and 13½@13¾c. for electrolytic. Casting is nominally 13¾@13¾c. cents.

Copper sheets, cold-rolled, 20c.; hot-rolled 19c. per lb., base. Copper wire, 15¾c. base, carload lots at mill.

The London market broke sharply every day of the week, until Tuesday morning, when £59 12s. 6d. for spot and £60 10s. for three months was touched. From this point there was a feeble rally, and the close is easy at £60 7s. 6d. for spot and £61 5s. for three months.

Refined and manufactured sorts we quote: English tough, £64; best selected, £63@64; strong sheets, £75@76.

The disparity between the New York and London markets was such on Monday last that cathodes could be bought in London out of storehouse and be delivered in New York at 13½c. per lb., while the price here was 13¾c. However, it is improbable that any such return movement will

occur, the chances being that the disparity will be removed by a rise in the London price, or a fall in that of New York.

Exports from New York and Philadelphia for the week are reported at 4213 long tons copper. Our special correspondent gives the exports from Baltimore at 801 long tons.

Imports and exports of copper in Germany, 11 months ended Nov. 30, metric tons:

	1907.	1908.	Changes.
Imports.....	120,753	147,114	I. 26,361
Exports.....	9,813	8,034	D. 1,779
Net imports.....	110,940	139,080	I. 28,140

The increase in net imports in 1908 was 25.3 per cent.

Tin—The firmer tone which London reported middle of last week was not maintained, and the market relapsed into dullness. Transactions were of small volume at declining prices. At the close, quotations reacted somewhat and are cabled at £126 15s. for spot and £128 12s. 6d. for three months.

Consumers in this market are attracted by the lower prices and are showing some interest. So far, large transactions, however, have not taken place. The market is quoted at about 28 cents.

Arrivals of Bolivian tin ores and concentrates—chiefly concentrates—in Europe for the 12 months ended Dec. 31 are reported 15,394 long tons in 1907, and 17,632 tons in 1908; an increase of 2238 tons.

Lead—There has been no change in the market, quotations being easy at 4.15@4.20c., New York.

The London market presents no new features and closes unchanged at £13 2s. 6d. for Spanish lead, £13 5s. for English lead.

Spelter—There is a little more pressure to sell, and as the demand is of small proportions prices have eased off somewhat, and close at 5.12½@5.15c., New York, and 4.97½@5c., St. Louis.

The London market is also somewhat lower, and quotations are cabled at £21 2s. 6d. for good ordinaries, £21 7s. 6d. for specials.

Base price of sheet zinc is 7c. f.o.b. La Salle-Peru, Ill., less 8 per cent.

Other Metals

Antimony—The market is quiet, with little doing in the way of sales. Quotations are a shade lower, at 8¼@8½c. for Cookson's; 8@8½c. for Hallatt's; 7½@7¾c. for ordinary brands.

Aluminum—There is no change in the condition of the market. The European situation is still demoralized, prices being down to the cost of production. Foreign

aluminum has been sold in New York at 21½¢. per lb. for ingots. The Aluminum Company still quotes 24¢. base for No. 1 ingots and 33½¢. base for sheets.

Some large bids have recently been made for aluminum wire in electrical work. A contract for transmission wire for a Manitoba power company which would require 1,350,000 lb. of copper wire has been taken by the Aluminum people at a price not made public. Deliveries on this contract will extend over some time. Another contract in Massachusetts, which would take 450,000 lb. of copper wire, has also been taken by the Aluminum people.

Quicksilver—The market is quiet. New York quotations are \$45@46 per flask of 75 lb., showing no change. San Francisco prices are \$45@46 for domestic orders, and \$43@44 for export. London quotation is £8 7s. 6d. per flask, with £8 6s. 3d. named by jobbers.

Nickel—Large lots, contract business, 40@45¢. per lb. Retail, from 50¢. for 2000-lb. lots up to 55¢. for 500-lb. lots. These quotations are for spot nickel. The price for electrolytic is 5¢. higher.

Cadmium—In 100-lb. lots, 75¢. per lb., at Cleveland, Ohio.

Magnesium—This metal is offered in New York at \$1.25 per lb. in 100-lb. lots. The price is \$1.40 per lb. for 5-lb. lots.

British Metal Imports and Exports

Imports and exports of metals in Great Britain, 12 months ended Dec. 31, figures in long tons, except quicksilver, which is in pounds:

	Imports.	Exports.	Excess.
Copper, 1907.....	166,348	68,866	Imp. 97,482
Copper, 1908.....	129,061	66,375	Imp. 62,686
Tin, 1907.....	47,730	42,096	Imp. 5,634
Tin, 1908.....	43,794	35,435	Imp. 8,359
Lead, 1907.....	237,518	194,464	Imp. 188,054
Lead, 1908.....	204,695	137,372	Imp. 161,323
Spelter, 1907.....	108,519	8,417	Imp. 100,102
Spelter, 1908.....	109,172	6,353	Imp. 102,819
Quicksilver, lb.:	3,270,412	1,076,167	Imp. 1,594,245
Quicksilver, '07 2,958,603	2,209,439	Imp. 748,664	
Ores.			
Tin ore and cobalt.....	25,013		Imp. 25,013
Tin ore, 1907.....	30,871		Imp. 20,871
Pyrites, 1907.....	759,910		Imp. 759,910
Pyrites, 1908.....	769,141		Imp. 769,141

Copper totals include metallic contents of ore and matte. Exports include re-exports of foreign material. Of the imports in 1908 the United States furnished 7068 tons copper matte, 56,138 tons fine copper and 36,443 tons lead.

Zinc and Lead Ore Markets

Platteville, Wis., Jan. 16—The base price paid for zinc ore this week was \$41@42.50 per ton of 60 per cent. zinc; no premium price is reported. For 80 per cent. lead ore \$50 per ton was paid.

The shipment was largely reduced the past two weeks by temporary shutdowns for repairs by a number of the larger producers.

Hazel Green failed to report. There is included in the week's shipments 28,000 lb. from Mineral Point, 63,000 from Harker, 101,010 from Linden and 116,100 from Highland; in all 309,010 lb. zinc ore shipped in the previous week, but not then reported.

Year to Jan. 16.....	6,472,996	60,000	562,900

Shipped this week to the Platteville Separating Company, 367,650 lb.; to the Joplin Separator Works, from Rewey, 108,000 lb. zinc ore.

Joplin, Mo., Jan. 16—The highest price for zinc ore was \$40, the base price being \$44 and \$43 for the bulk of the ore sold, with a few small bins sold at \$42 per ton of 60 per cent. zinc, for sulphide ore. Silicate ore sold on a base of \$10 per ton of 40 per cent. zinc, with sales as high as \$24, on a flat bid. The average price, all grades, was \$39.78. Lead advanced this week to \$54.50 per ton, an increase of \$2.

Note.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the third and fourth the average for all ores sold. Lead ore prices are the average for all ores sold.

The average price, all grades, was \$51.90 per ton.

A snowfall of 12 in. last Monday, with 7 deg. below zero on Tuesday put a large number of mines out of business for the greater part of the week, and it is estimated that the output was only approximately 30 per cent. of normal. The shipment is the smallest in years. A number of producers declined to sell under a base price of \$45, and the buyers seemed equally determined not to pay this price. This, with the heavy snow, made the shipment light. A large proportion of the ore shipped is from purchases of the previous week.

Chemicals

New York, Jan. 20—The market in general is steady with no changes of importance. Stock-taking is hardly completed yet, and buyers do not seem ready yet to do business beyond their immediate needs.

Copper Sulphate—Demand is fair and no shading is reported, there being little outside stuff on the market. Quotations are steady at \$4.75 per 100 lb. for car-load lots and up to \$5 per 100 lb. for smaller parcels.

Arsenic—The market is dull, only a few small sales being reported. Quotations are 3¼¢. per lb. for white arsenic.

Nitrate of Soda—Comparatively little is doing in this article. Current quotations are 2.17½¢. for spot and 2.12½¢. for futures.

Mining Stocks

New York, Jan. 20—The general stock markets have been largely professional in their character, with outside dealing not at all heavy. Fluctuations have been moderate, the only considerable decline having been in Amalgamated Copper. This stock rallied a little at the close. There was nothing of importance to affect the course of the market seriously in either direction, and it was not specially interesting.

On the Curb there was a fair amount of trading in copper stocks, Cumberlandly being the leader. While prices were not strong, they held up better than might have been expected. In the first part of the week Standard Oil was forced down, but it rallied toward the close. The Cohalt stocks were in fair demand, and prices held well, with a good volume of trading. The Nevada stocks were not specially active.

Boston, Jan. 19—It has been a dull and monotonous market, and outside of a few exceptions price changes have been unimportant. The weakness of copper metal has had to do with this state of affairs, which, to say the least, is discouraging for the moment.

New York and St. Louis, cents per pound.
London in pounds sterling per long ton.

Electric Shot-Firing in Coal Mines

Discussion of a System Installed in Utah, Where All Shots Are Fired from the Surface after the Workings Are Clear of Men

B Y D. HARRINGTON*

Fully as beneficial as the arrangement for spraying is the electric shot-firing system, which, by causing all shots to be exploded after every man, including shot-firer, is out of the mine, thus prevents the numerous accidents due to blowout, or windy-shots, falling roof, or coal, caused by successive concussions from shots which are fired when men are in the mine; this plan also insures the safety

the electric generator, to the mouth of the return air course, the feed wires of No. 6 rubber-covered or weather-proof wire, are strung on ordinary pine or cedar poles, 16 to 18 ft. long and equipped with short cross arms.

From the mouth of the manway or any opening in which the wires are not likely to be disturbed by haulage devices, falling roof, etc., these two feed wires are car-

and 14 wires may be fastened by means of 3-wire porcelain cleats, placing the wires in the two outside grooves; these cleats are fastened to props, legs, caps of timber, or to wooden plugs driven into holes previously drilled into roof or rib, such supports being placed 25 or 30 ft. apart or sufficiently close to insure that wires will not touch each other if the insulation should wear or rot off.

CRUSHER, TIPPLE AND TRESTLE AT THE SUNNYSIDE MINE OF THE UTAH FUEL COMPANY, IN UTAH

of all human lives in case of a general explosion which may be caused by such concussion, or windy-shot.

SHOT-FIRING SYSTEM AT THE CASTLE GATE MINE

A successful system of electric shot-firing is installed in the Castle Gate mine of the Utah Fuel Company. Considerable gas has been encountered in the development of this property. The shot-firing scheme here inaugurated has been a working success for more than a decade. The same method is also a working success in the Sunnyside No. 1 mine, where gas has always caused much annoyance. From the central power plant containing

ried through some opening which approximately divides the mine into halves, or which will at any rate allow of practically uniform length of auxiliary lines in order to insure symmetrical distribution of current. These auxiliary lines are of No. 12 rubber-covered wire and are run from the main feed wires through the main haulage entries to the mouth of the rooms, thence No. 14 rubber-covered wire to the working faces. These wires should be taken through any opening which is likely to be well kept up. In most cases, haulageways are well preserved, and in such entries the wires should be strung as far as possible from the track and close to the roof. The main, or No. 6 feed wires should be supported on posts wedged between roof and floor and spaced about 20 ft. apart; the actual fastening of the wires to the post should be a small iron bracket and glass insulator. The Nos. 12

ARRANGEMENT OF WIRES BEFORE SHOOTING

The coal is either undermined or overcut by hand, and giant powder, about 40 per cent. nitroglycerin, is used to bring down the coal; less than 1/10 lb. of powder is used per ton at Sunnyside, and less than 1/5 lb. at Castle Gate; the Castle Gate coal is hard and is used largely as domestic fuel, therefore the market for this coal demands a minimum of fines, while the Sunnyside coal, not so hard, is used for coking purposes, and consequently, the slack can be utilized to advantage. "Reliable" exploders are used, these being provided with two insulated wires each 6 to 8 ft. long. These exploder wires, bared of insulating material, are attached to the No. 14 rubber covered room wires, before mentioned, by the miner just previous to leaving his working place for home, the connections are made in parallel to insure the firing of at

NOTE.—A sketch of the Sunnyside mine in Utah, showing the plan of wiring for the shot-firing system here described, was published on page 193 of THE ENGINEERING AND MINING JOURNAL of Jan. 23.

*Mining engineer, Salt Lake City, Utah.

least part of the round of shots in case an exploder may be defective while if connected in series, one defective exploder would prevent the firing of the entire round. In making wire connections, loops should not be allowed; all wires should be bared and twisting resorted to, several turns being made to insure good contact.

THE SHOOTING SWITCH

Switches should be placed so no shot can be fired without previously throwing three switches into contact, all switches should be placed in locked boxes with key in possession of shot-firer. At the power plant, the engineer in charge of the generator is in charge of one locked switch, this latter being out of contact until after all men are out of the workings. This same locked switch is thrown out again as soon as the shots have been fired. The main shooting switch is placed in a small cabin near the mouth of the mine, but

Gate and Sunnyside, a 500-volt continuous current is used. The generators in both places were installed for haulage purposes before shot-firing by electricity was contemplated; the additional power required for shooting is trivial, being only used for a few seconds daily after haulage operations have been suspended.

THE SHOT-FIRER'S DUTIES

In operation, the services of the following are required: A checkman, a man who acts as wireman and shot-firer, and the fire-bosses or inspectors; the checkman and the shot-firer may be charged totally to the shot-firing system, while the services of the inspectors, or fire-bosses are merely incidental to their ordinary duties.

The checkman's duties are physically light, hence for the purpose, an employee who has been injured in the company's service will answer, provided he can be

must report to get assurance from the inspector as to the safety of their individual working places.

Upon receiving such assurance, the employee, day hand, or miner, will, before entering the mine, deposit his check or tag with the checkman; this check bears the miner's number, which must correspond with the number of that man on the company's books at the mine office, and to the number on the check which the miner places on the car of coal loaded out by him to establish ownership to that car. Failure to deposit this check will subject the offender to dismissal, and failure on the part of any day hand may also cost him his day's pay, as the checkman keeps the time of the day hands from checks deposited with him; when no check is deposited, no time is credited.

These checks are placed on a board having corresponding numbers, and kept in the check house under the care of the checkman, who remains in the vicinity of the check house throughout the day. As each man leaves the mine, he receives from the checkman his check, thus accounting for all employees at all periods of the shift. The checkman occupies his time during the day by performing numerous physically light, but important and useful duties; he keeps a book having the name and number of each miner together with his working place, nationality, regularity of attendance at mine, etc., from which the mine officials may obtain much timely information. The checkman can also oil and otherwise look after the fan, if the latter is located near the check house; he can clean and fill safety lamps where used, keep a record of barometer and thermometer readings, etc.

The fire-bosses, or gas inspectors, perform the usual duties as underground inspectors, and each employee must report to the fire-boss before entering the mine for his day's work. If during the underground inspection the fire-boss has found any missed shots, he is required to bar entrance to the place with a notice warning all persons to keep out; on coming to the surface he will not permit the miners in that particular place to go to work, at the same time informing the shot-firer of the location of the missed shot. The shot-firer will, during the day, inspect this place, and upon discovering the trouble, will make the shots ready to be fired with the regular round that night; if they fail a second time, it is the duty of the fire-boss to investigate and inspect the holes after all shots are fired; a third failure of the shots renders it necessary for both shot-firer and inspector to remain after shot-firing on the third night until these shots in question are put off.

THE CAUSE OF MISSED SHOTS

Unless shots or wires are tampered with maliciously, failure twice in succession is rare. The usual cause of a missed shot

THE CLEAR CREEK STORE AND HOUSES OF THE UTAH FUEL COMPANY

removed from direct line of all openings in order to insure safety of shot-firer in case of explosion; this cabin is used for no other purpose than the housing of this switch; it is substantially built and is kept locked, with access to no one except the shot-firer.

There is also a switch controlling each auxiliary No. 12 wire line, this switch being placed in a locked box located near the point where the connection of auxiliary line is made to feed line. Each of these switches controls a shooting district, and is kept locked with a key in the hands of a shot-firer. All switches in connection with this system are of the knife variety, with knife or lever dropped down out of contact, in order to prevent any possibility of accidental closing of the switch by jarring, etc.; this latter detail may seem trivial, but is most important in possible results.

Current is supplied from the central power plant in each camp; at both Castle

thoroughly trusted. The checkman should be at the powder distribution house shortly after 6 a.m., and have instructions to give out only a certain amount of explosive to each man ($6\frac{1}{4}$ lb. per man is the maximum amount which can be kept in the mine in one place by provision of the State law). As $6\frac{1}{4}$ lb. will bring down at the Sunnyside mine more than 80 tons, the actual amount here allowed per man is but one or two pounds. After giving out powder, the checkman goes to the check cabin which is situated close to the mouth of the manway, and if possible close to the mine ventilating fan; his position should be such that he will have a view of the mouth of the main haulage-way and tippel, but always out of direct line of any mine opening. To this check cabin, the fire-bosses, or gas inspectors, also come to make their report of the morning's shooting, which is always done before any employee may enter the mine. To this cabin, also, all employees

is generally due to failure on the part of the miner to correctly connect the exploder wires to the No. 14 room wire, or to a fall of roof breaking the wires. Since failure of shots means loss of the next day's work to the miner, even the most ignorant will scarcely repeat such error after having been shown the correct method, and as there is a lapse of not more than an hour between the departure of the miner and the firing of shots, roof falls are not at all likely to cause much trouble.

LOADING THE HOLES

The fire-boss' connection with firing ceases from the time the men enter the mine in the morning until in the afternoon when he carries a supply of caps, or exploders, to each working place; the miners have previously drilled the holes and otherwise prepared for the loading of same with minimum delay for the fire-boss. The latter makes certain that the holes are free of dust, are not deeper than the undermining, are not too close to roof, or rib, etc., and proceeds to load the holes by first throwing into the back of the hole a handful of wet wood pulp which has

Any tampering with the loading after the departure of the inspector will, of course, subject the offender to dismissal if apprehended; the exploder wires are not connected to the No. 14 room wire by the miner until he is ready to leave for home, and knowing his next day's work depends on the correctness of this connection, very few missed shots are traceable to the miner's carelessness. Below is a copy of the shooting regulations as posted at the Castle Gate mine:

SHOOTING REGULATIONS IN UTAH

(1) The mining must extend at least 6 in. beyond back of holes in all cases, and 12 in. at all places beyond and toward the right side of the holes.

(2) All holes must be at least 2½ ft. in length. No shorter holes will be fired.

(3) All coal dust must be extracted from holes before they are fired.

(4) No holes must be charged with more than 5 sticks of powder. (1¼ lb.)

(5) No material whatever except the wet wood pulp furnished by the company must be used in tamping holes.

(6) No shots will be fired unless all places within 30 yd. of the hole are in a

the morning, to throw out of contact all switches which were thrown into contact for the firing of the previous night's round; when all switches are thrown out of contact and containing boxes are securely locked with the only existing key in the possession of the shot-firer, all precautions have then been taken to prevent the accidental discharge of any shots which may for any reason happen to be connected at the face; the switch at the power house is in contact only for a few minutes per day and then only when all men are out of the mine; the switch by which final connection is made at the shooting cabin is likewise in contact only a few seconds daily, and the switches controlling various auxiliary circuits in the mine, which have been in contact over night, are thrown out before any men are allowed to go into the mine.

During the day, the shot-firer becomes wireman, and goes through the mine carrying various materials for extension or repairs where needed; when the time arrives by which the men should be out of the mine, he throws all underground switches into contact for all circuits where holes are to be shot. The shot-firer next

GENERAL VIEW OF THE CASTLE GATE TIPPLE AND COKE OVENS

THE WINTER QUARTERS MINE AND SIDINGS

been procured by the miner from the company supply, placed in barrels and located at convenient points underground. The cost of this pulp is about \$25 per ton. The fire-boss next takes powder from the miner, attaches the exploder, or cap, which is accomplished by tying the powder with a half hitch of the wires with which the exploder is provided; he then places powder and cap in the hole and proceeds to tamp a few handfuls of wet wood pulp upon the powder; this process is repeated for each hole, leaving the miner to complete the tamping.

The inspector thus has complete supervision over the loading of each and every hole, being final judge as to the amount of powder to be used, giving out only as many caps as there are holes, etc.; he may also refuse to shoot any hole which he deems in any manner dangerous. Wet wood pulp is used in tamping because a State law prohibits the withdrawal or reopening of a missed shot unless "*such holes are tamped with wet wood pulp*," and while it is necessary to open but few shots, still when such a case occurs, it is not well to defy the law.

wet condition, so that dust cannot be raised by a windy-shot.

(7) Standing holes or parts of standing holes will not be recharged.

(8) The hole in a "tight" corner must be at least 1 ft. from rib at back of hole.

(9) In solid faces, holes must not be more than 5 ft. apart horizontally and not less than two such holes will be fired.

(10) In coal over 6 ft. high, no hole must be more than 5 ft. in height above the floor at back of hole, in shooting bottom bench.

(11) In high coal, bottom bench must be shot down before shots are fired in the top bench.

(12) The object of the above rules is to prevent and remove the danger from blow-out or windy-shots and it should be the duty of all firemen in addition to the above rules, to refuse to shoot any holes which in their judgment may be dangerous, whether the circumstances are fully covered by the rules or not. The firemen are expected to always be on the safe side.

The shot-firer, who is also wireman, must go into the mine sufficiently early in

goes to the check cabin to ascertain from the checkman whether all men are actually out of the mine. If the checkman's board is bare, he knows the "coast is clear," and proceeds to the shooting cabin, which is located in a safe place; here he throws the main switch making the final closing of the circuit. After leaving the switch in contact for two or three seconds, the circuit is again broken *not to be again closed until the next night*, the cabin is securely locked and the shot-firer goes home. The engineer at the power house knowing from his ammeter that the shots have been fired, opens his switch and the entire shooting system is totally devoid of current for another day.

If, however, on coming out of the mine, the shot-firer is informed that men are yet underground, and that no known emergency exists for their being there, he gets from the checkman the location of their working place, goes into the mine and on locating them, fires the shots as soon as they are out. If his search in the mine is vain, a search through the camp is instituted and when the men are found and *not until then*, shots are fired.

It is important that both checkman and shot-firer are sober, conscientious men, neither position being one to be filled by boys or irresponsible relatives or personal friends of mine officials; the checkman need not be physically perfect, but the wireman should be a wide-awake conscientious man, preferably of middle age, with great power of endurance and incapable of shirking. The position should be well paid and appointment to it should be solely as a reward of merit.

COST OF INSTALLATION

The cost of installing a shot-firing system is much less than the expense incurred in completing a spraying system. At the Sunnyside No. 1 mine, with an annual production of about 300,000 tons, the installation of a complete shooting plant, excluding source of power was \$1250, of which \$850 was for material, which comprised 6000 ft. of No. 6 rubber-covered wire, 26,000 ft. of No. 12 rubber-covered wire, 30,000 ft. of No. 14 rubber-covered wire, 10 switches with locked boxes for same, 16-ft. poles, cross-arms and insulators for 1200 ft. of surplus line, shooting cabin on surface, and brackets, insulators, porcelain cleats, etc., for 30,000 ft. of underground line. The line to No. 2 mine at Sunnyside, cost but \$640, the low cost being due to the fact that no poles, etc., were necessary for the main feed line; the feed wires were strung on poles already in place and carrying power into the mine for electric hoists and electric locomotives; the installation of a separate line, however, is generally advisable, so as to remove shooting wires from the danger of being charged by possible accidents to other power lines which carry current during working hours.

The \$1250 expenditure for the No. 1 mine installation, if paid by one year's output of that mine, 300,000 tons, would add but 2½¢. per ton to the cost. In operation for the same sized mine, producing 300,000 tons annually with 275 days worked, there would be a checkman at \$75 per month amounting to \$900, and a shot-firer or wireman, 275 days at \$3.25 per day, amounting to \$893.75, a total yearly labor operating cost of \$1793.75; add to this \$100 for material, which would be ample, and \$1000 will cover the entire charge of this system against 300,000 tons, or an addition to the cost sheet of less than 2½¢. per ton, certainly not an item that any mine operator should fear.

OBJECTIONS TO THE SYSTEM

Objections to the shot-firing system have been advanced as follows: Output must necessarily be restricted through missed shots; the concerted action of so many shots must have harmful effect on roof causing excessive expense to keep roof up and to keep haulageways clear; ventilation must be disarranged by falling roof and by heavy concussion, and lastly,

the presence of explosive gas would prevent successful use of such a system.

As to a decrease of output, experience has shown that on the installation in a mine with a daily output of over 1000 tons, after the newness has worn away and miners understand the correct method of connecting exploder wires to shooting wires, the percentage of missed shots is but 1 per cent.; on an annual output of 300,000 tons, 1 per cent. is 3000 tons and if the coal company clears one dollar per ton, the shooting system should be charged with \$3000 annually, *not lost* but the receipt of which is deferred; if money is worth 6 per cent., we have here an actual charge against the shooting method of \$180 yearly.

The general belief is that the resulting concussion caused by the firing of 200 or 300 shots simultaneously is at least approximately 200 or 300 times as great as that of one shot; this is, however, erroneous as the resultant concussion is less than the aggregate of the three or four shots which constitute a round at each working face. These working faces are 50, 75 or 100 ft. apart and the waves sent through all surrounding territory by the different concussions, radiate in all directions; these waves meet each other and are partially neutralized.

No inspection of underground conditions is made from the time of firing shots, which is about 5 p.m., until 3 or 4 a.m., a lapse of 10 or 11 hours; the fire-bosses seldom report any derangement of ventilation devices, such as open doors, etc., nor is there excessive falls of roof on haulage tracks during this time. The fact that there is but one concussion per day, rather than a continual succession of jars, tends to prevent the shaking loose of the roof, and for this reason, the system is really more applicable to mines with clay roof than to workings with a hard sandstone roof like that at Castle Gate and Sunnyside.

THE SYSTEM CAN BE USED IN GASEOUS MINES

The presence of explosive gas is the most serious objection to the installation of such a system; however, the plan has for years been successfully operated in the most gaseous mines of Utah, one of which has at times been worked with safety lamps exclusively. In the gaseous mine at Sunnyside, absolute and unqualified success has attended the operation of the system; it is true that a violent explosion occurred at Castle Gate after the shot-firing scheme had been inaugurated there; however, this very fact only emphasizes the correctness of its principle, for not a single human life was sacrificed, and the good name of the mine was preserved. It has been stated that this explosion was the result of the bad judgment of the shot-firer in throwing his lever a *second* time into contact after

having made a first contact; however, whether the explosion was caused by the first contact or by throwing the lever a second time cannot be definitely stated.

THERE IS BUT SMALL LOSS OF TIME

It is also advanced that labor trouble may be precipitated because of lost time from missed shots, which latter prevent the miner whose shots failed, from working the following day. Where installed correctly and carefully operated, the missed shots aggregate only about 1 per cent., and as most of these are the fault of the miner himself, successive misses are rare. Moreover, when the miner becomes accustomed to the system, and realizes that it renders him absolutely safe from blowout or windy-shots and their attendant dangers, also that he can go into the mine in the morning breathing air free from head-splitting powder smoke, and come out at night without having so much as had a whiff of that arch enemy of all miners, he is indeed an obdurate individual who cannot look with equanimity on the occasional loss of a day's labor.

The installation of well devised spraying systems in the mines of Utah has rendered most of these operations practically nonexplosive; also the installation of both the spraying system and the electric shot-firing system in the gaseous mines has freed the underground employee as well as the mine official from many of the ordinary anxieties which always accompany underground colliery work.

When the commission of foreign colliery experts who came to the United States to investigate our methods, presumably to instruct us how to improve them, had inspected the Utah mines, they were enthusiastic in their praises of the life-preserving systems here installed, and while they roundly condemned the dangerous dustiness of Western mines, they carefully excluded Utah mines from this execration. The Utah coal operators have had abundant proof that instead of being "out of pocket" to the extent of 1, 2, or 3¢. per ton produced, they are in fact the gainer to the extent of several thousand dollars annually, and possibly to a much greater extent in disasters prevented.

The cause of the so-called burning of dynamite is obscure. E. A. Mann, chief inspector of explosives for Western Australia (*Journ. Chamber Mines, West Australia*, July 31, 1908), states that it is doubtful whether the explosive frequently, if ever, actually catches fire in the hole. It seems probable to Mr. Mann that the formation of fumes is due to the fact that the initial impact of the detonator is insufficient to penetrate to the extreme limits of the charge.

Mineral Production of British Columbia in 1908

Returns Show an Estimated Decrease of \$2,025,000 in Total Value with an Increase in Lode Gold, Copper, Silver and Zinc

B Y E . J A C O B S *

The mineral production of British Columbia for 1908 shows an estimated decrease of \$2,025,000 in total value as compared with that of 1907. In quantities of individual minerals produced, though, there are in several instances increases, the exceptions being in placer gold, lead and coal, respectively. On the other hand, lode gold made an increase of approximately 60,000 oz.; silver of 291,500 oz.; copper of 3,053,000 lb.; zinc of 8,000 tons; and coke of 25,000 tons, while building materials, etc., are estimated at \$50,000 higher in total value. Of the total decrease shown, \$146,000 is in placer gold, \$1,730,000 in lode metals, and \$149,000 in non-metalliferous minerals.

Revised returns will probably show several changes, among these in copper which would appear to be shown at less than the actual production. However, the estimate which follows has been based upon information obtained chiefly direct from the larger mines of the province, and so far as many of the small silver-lead mines are concerned, from production statistics published in local newspapers. These latter are always difficult to obtain unofficially, so that information is generally incomplete until after the owners and lessees of small mines have sent in to the provincial Bureau of Mines returns which admit of the actual production of various districts being ascertained and made public.

The figures showing the production of coal and coke may be taken as approximately correct, since they have been obtained from the companies making the greater portion of the production of the province in these minerals. Unimportant changes will probably result when several new companies that have been producing on a small scale have sent in their returns for the year.

In regard to the total production of individual districts, the Boundary district (which is included in that officially known as Yale) has maintained its lead over West Kootenay, though not to so great an extent as in the years 1906 and 1907, respectively. It will be observed by reference to one of the accompanying tables that while West Kootenay made an increase in 1908 as compared with 1907 of \$917,700, figures for the Boundary show a decrease of \$1,360,000. This decrease, though, is attributable entirely to the fall in the price of copper, which notwithstanding

ing that the production of that metal in the Boundary was increased by about 4,500,000 lb., the value of the year's product was lessened by \$1,552,000 by the reduction of the average market value for the year of copper in New York to the extent of practically one-third as compared with that of 1907. The Coast was third on the list in 1908, decreases in both copper and coal production being accountable for its having given place to West Kootenay for second place. East Kootenay, which in 1907 was third in point of total value of mineral products, took fourth place for 1908. Here, too, there is a particular reason; namely, a reduction by about one fourth in the average price of lead for the year, which caused the suspension early in the year of one lead mine and a reduced production at another, the latter being the largest producer of this metal in the province.

Apart from the fall in prices of metals, there was little to retard progress during the year, the chief exception having been labor troubles for a few weeks at Crow's Nest Pass coal mines in East Kootenay. At all the metalliferous mines and smelting works that were operated, wage questions were settled either at the close of the previous year or in the early part of that under review, and no fresh difficulties were experienced during the remainder of the latter period.

Following the method of calculation used by the British Columbia Bureau of Mines, the average prices for the year of silver, lead and electrolytic copper in the New York metal market, as near as practicable, have been taken as a basis, less deductions of 5 per cent. off silver and 10 per cent. off lead. The several prices used are as follows: Gold, placer, \$20 per oz.; gold, lode, \$20.67 per oz.; silver, 50c. per oz.; lead, 3.78c. per lb.; copper, 13.2c. per lb.; coal, \$3.50 per ton (2240 lb.); and coke, \$6 per long ton.

GOLD

The production of placer gold in 1908 was still more disappointing than in 1907, which in turn gave the smallest production up to that time of any year since 1908. In like manner it must now be said of 1908 that its total of this metal was the lowest since the earlier year mentioned. The greater part of the decrease was in Cassiar district, the estimated shortage from Atlin division of that district having been \$183,000, and of the Liard and Stik-

ine divisions \$25,000. Individual miners produce comparatively little gold in Atlin camp now, and for one reason or another the hydraulic companies recovered much less gold last year than in several previous years. There is, though, much gold-bearing gravel still available on three or four of the Atlin creeks, so it is to be expected that with an adequate water supply, which has recently been provided for by one or two of the larger producers of the camp, a much better result will be obtained next season. The three divisions of the Cariboo district are each credited with an increase, as shown in the last of the tables, their mineral production being entirely placer gold. The Similkameen division of Yale district appears to have increased its yield by \$9000, but Lillooet shows \$7000 less than in 1907. The figures for the Kootenay districts and the Coast do not exhibit any changes of production of placer gold, in comparison with that of the year immediately preceding.

The decrease shown against Cassiar district is partly the result of the transfer of a portion of Skeena mining division to the coast district, while that of Lillooet is the result of a temporary stoppage of dredging on that part of the Fraser river.

In lode gold the largest proportion of

the increase was made in Trail Creek division, in which three mines at Rossland each produced more gold than in 1907, their total increase having been rather more than 48,000 oz. In Yale district the Boundary mines yielded about 12,800 oz. more, this having been gold occurring in association with copper. Nelson division contributed 800 oz. to the total increase, and a small addition was reported from a mine in the Lardeau section of West Kootenay. The decreases were in the Coast district, chiefly from the copper-gold mines having a greatly reduced production consequent upon a suspension of work during quite half of the year. To the total of 256,000 oz., Rossland mines contributed about 142,000 oz.; Boundary mines and Hedley camp of Osyoos division together about 94,000 oz.; Nelson (mostly from Sheep Creek camp), rather more than 14,000 oz.; the Coast (chiefly the Marble Bay mine, Texada Island), about 4000 oz., and the remainder from the Lardeau. Of the two larger gold mines of the province, the Ymte in Nelson division, and the

of the silver produced in East Kootenay last year came from one mine—the St. Eugene with two others contributing 50,000 oz. each, while in West Kootenay a dozen or more of the larger mines and a score or so of the smaller ones combined to make up the greater part of the production of the district. West Kootenay's production was from the following localities: Slocan, 953,000 oz.; Ainsworth division (which includes part of the district generally known as the Slocan), 330,000 oz.; Lardeau, 206,000 oz.; Rossland, 156,000 oz., and Nelson, 72,000 oz., together 1,742,000 oz. East Kootenay produced 675,000 oz., from St. Eugene, North Star and Sullivan mines. The Boundary district's proportion was 596,000 oz., chiefly from the copper mines of the Granby and British Columbia copper companies. The Coast district yielded 49,000 oz., nearly two-thirds of which was from the Marble Bay mine, Texada island, and a little less than one-third from the Ikeda mine on Moresby island of the Queen Charlotte group.

ketable metal content. More than three-fourths of that from the Lardeau last year was from the Silver Cup mine, with the True Fissure contributing nearly all the remainder from that district. In Nelson division the La Plata, and Silver King mines produced most of the silver from that division.

LEAD

The gradual decrease in quantity of lead produced in the province during three immediately preceding years was continued last year. The production for several years, as shown in the Annual Report of the Minister of Mines for British Columbia, was in round figures as follows: In 1905, 56,581,000 lb.; in 1906, 52,408,000 lb.; in 1907, 47,739,000 lb. Now comes a further decrease, for the estimated output for 1908 is but 43,775,000 lb., this being the lowest total since 1904, in which year it was about 37,000,000 lb. In the production of this metal East Kootenay leads with an output of 30,200,000 lb., or rather more than 69 per cent. of the whole, and this nearly all from the St. Eugene mine, of which, by the way, it may be mentioned that reporting last August the managing director of the Consolidated Mining and Smelting Company of Canada, Ltd., which owns this mine among others, advised the directors that "the probable ore reserves of the St. Eugene group are nearly 50 per cent. greater than a year ago. Ore 50 per cent. better in grade than last year's average has been found between the 600- and 800-ft. levels, on the main vein above the 1500-ft. level, and between the 1900- and 2000-ft. levels. In the report of last year it was mentioned that the 2000-ft. level did not promise to yield as much tonnage as the 1900-ft. level, but present indications are that the former will produce more ore than the latter, or any other level in the mine. The grade of the ore is, however, lower than that produced from the upper workings. Some bodies of low-grade material have been found on the 2100-ft. level, and a raise from this level shows ore of workable grade. Drifting and crosscutting on the 2200-ft. level are progressing, and one or two low-grade orebodies have been found. It will, however, require work for six months or a year to determine the amount of ore on this level." The ore concentrated last year in the St. Eugene mill averaged lower in lead and in silver than that in former years; it required 6.3 tons of ore to make one ton of concentrate. The aggregate of production of the St. Eugene mine for all years to June 30, 1908, was 684,311 tons of ore from which 138,878 tons of concentrate were made, which contained 3,951,141 oz. of silver, and 162,905,421 lb. of lead. The production for the calendar year 1908 was about 23,300 tons of concentrate and 2400 tons of ore shipped crude. The St. Eugene is the largest lead mine in Canada.

MINERAL PRODUCTION OF BRITISH COLUMBIA BY DISTRICTS AND DIVISIONS, 1907-1908.

Name.	Divisions.		Districts.	
	1907.	1908.	1907.	1908.
CARBIDEE DISTRICT				
Cariboo	\$306,500	\$350,000	\$360,500	\$420,000
Quesnel	44,000	50,000		
Omineca	10,000	20,000		
CASPER DISTRICT			572,809	225,000
EAST KOOTENAY DISTRICT			5,548,880	4,873,100
WEST KOOTENAY DISTRICT			4,792,976	5,770,550
Ainsworth	364,868	624,000		
Nelson	614,395	414,984		
Slocan	619,842	779,749

Other parts	144,169	166,824		
LILLOOET DISTRICT			15,721	5,000
YALE DISTRICT			8,444,326	7,160,245
Osyoos, Grand Forks and Greenwood	8,354,995	6,994,925		
Sinkikameen	56,564	135,000		
Yale	32,767	30,320		
COAST DISTRICTS			6,147,348	5,610,540
Totals			\$28,882,560	\$28,837,535

* The districts are shown in the order followed in the official reports of the provincial Bureau of Mines. Similarly, Rossland is included in the Trail Creek, and Greenwood and Grand Forks mining divisions, which constitute the district generally known in the province as the Boundary, are shown as in the Yale district, as is customary in the official publications.

Nickel Plate near Hedley, the latter is understood to have maintained its production on a similar scale to that of several recent years, but the former was practically a non-producer. The development of several small gold mines in Sheep Creek camp, was one of the features of progress in the year.

SILVER

The production of silver was larger in 1908 than in either 1906 or 1907. For the three years the several totals were: 1906, 2,990,000 oz.; 1907, 2,745,000 oz.; 1908, 3,037,000 oz. West Kootenay continues to hold its lead among the districts of the province producing silver, but since it includes a much larger extent of mining country than East Kootenay, which comes second, the comparison is hardly a fair one. Further, by far the greater portion

The very satisfactory increase made by the Slocan district, namely, of about 61 per cent., 953,000 oz. in 1908 as against 591,000 oz. in 1907, was contributed to in considerable degree by the Rambler-Cariboo, Richmond-Eureka, Ruth, Reco, Vancouver (now being operated by the Van-Roi Mining Company, organized in London early in the year), Standard, Hewitt, and Westmont mines. Ainsworth mining division made an increase of about 17 per cent., largely from the Whitewater and Whitewater Deep mines, in Whitewater camp, and in less degree from the Canadian Metal Company's Blue Bell mine, on Kootenay lake, at which a modern concentrating mill was completed last summer.

Silver from Rossland and Boundary district mines is chiefly obtained from ores also having copper as an important mar-

The approximate lead production of West Kootenay was as follows: From mines in Slocan and Ainsworth districts, 12,000,000 lb.; Nelson, 650,000 lb.; Lardeau, 900,000 lb., and Boundary, 25,000 lb. The chief producers in Slocan were in order of quantity, the Standard, Rambler-Cariboo, Richmond-Eureka, Ruth, Vancouver, Reco, Slocan Star, and Sunset; in Ainsworth division, the Blue Bell, and Whitewater (the product of the Whitewater and Whitewater Deep mines combined); in Nelson division, the Emerald and La Plata; and in the Lardeau, the Silver Cup (Ferguson Mines, Ltd.).

The term for which the Lead Bounty Act of 1903 was operative expired on June 30, 1908. The amount of bounty paid by the Dominion of Canada government under its provisions was \$712,000, leaving of the amount originally provided for (namely, \$2,500,000) an unexpended balance of \$1,788,000. During last year's session the Parliament of Canada passed legislation authorizing a continuance of payment of the bounty for another term of five years until June 30, 1913. The new act differs from the old in that the full rate of bounty (75c. per 100 lb. of lead), is payable until the price of pig lead in London reaches £14, 10s. per ton of 2240 lb., instead of £12, 10s. as under the old act, when the amount of bounty is diminished proportionately to the excess in price above the former amount mentioned. The old act was intended to guarantee the producer of lead in Canada a steady price of £16 per ton, equal to about \$2.50 per 100 lb. of lead. The new act practically raises the price £2 per ton, equal to about 43c. per 100 lb. The new act does not otherwise differ from the old. The full rate of bounty has been continuously payable since the coming into force, on July 1, 1908, of the new act, and the amount of bounty earned by lead producers under it has been about \$30,000 per month to the close of the year. G. O. Buchanan, of Kaslo, B. C., Dominion supervisor of lead bounties, is authority for this information concerning the lead bounty.

In connection with the production of lead it may be added that while the lead smelter of the Hall Mining and Smelting Company at Nelson, remained closed all the year, and that of the Sullivan Group Company at Marysville, East Kootenay, was closed in February and has not since been operated, the Consolidated Mining and Smelting Company of Canada has increased both the smelting and refining capacity of its lead reduction works at Trail, which are being regularly operated. Two more Huntington-Heberlein roasting furnaces (making six in all) have been installed, a new anode plant put in, and the refinery enlarged to a capacity of about 75 tons of refined lead per day. The company has also made a number of changes and improvements at its concen-

trating mill at the St. Eugene mine, whereby an increased saving has been made.

A concentrating mill embodying the latest methods for the separation of lead and zinc from the iron and other gangue of the ore was erected and fully equipped at the Blue Bell mine, Kootenay lake, this mill having been designed by S. S. Fowler, of Nelson, general manager for the Canadian Metal Company, which also owns the Blue Bell mine. In this connection it may be stated that there now being in that mine a sufficient tonnage available and probable to justify expenditure which will insure stability of the plant, this has been provided for by making the foundations of the mill of concrete and its frame of heavy timbers. The general arrangement of the plant is such as to permit of large increase of capacity at relatively small expense. In detail the planning of the mill has not involved any radical departures from well established lines of ore dressing, although there have been introduced a number of minor innovations. As a corollary, the general scheme of development of the mine adopted has been such as to make practicable its exploitation at low cost, thereby insuring the extraction of the ore under conditions especially favorable to profitable results.

COPPER

The year's production of copper, estimated at 43,885,000 lb., is the largest by nearly 1,000,000 lb., of any year since copper mining was commenced in the province, that of 1906 (42,990,000 lb.) having previously been the maximum production for one year. Of the total for 1908, Boundary district mines produced about 36,000,000 lb.; those of Rossland came next with 5,300,000 lb., and the Coast mines with about 2,500,000 lb. The production of other parts of the province was insignificant.

The progress of copper mining in the Boundary will be evident from the following figures of annual production, those in parentheses being for the whole of British Columbia: In 1904, 22,066,000 lb. (35,710,000 lb.); 1905, 27,670,000 lb. (37,692,000 lb.); 1906, 32,227,000 lb. (42,990,000 lb.); 1907, 31,521,000 lb. (40,833,000 lb.); 1908, 36,000,000 lb. (43,855,000 lb.). Assays of copper ores of the district, based upon copper recovered in 1907, averaged 1.34 per cent. copper. As there is not a very great difference in the general copper content of the respective ores from the several large mines of the district, an idea of the quantity of copper produced by each company is obtainable from the following figures showing tonnage of ore mined and smelted last year: Granby Company, 1,023,000 tons; British Columbia Copper Company, 358,000 tons; Consolidated Mining and Smelting Company,

41,000 tons; Dominion Copper Company, 22,000 tons (the last mentioned company operated its smelter only a few weeks, going into liquidation last summer). This gives a total of 1,444,000 tons of copper ore mined and smelted in the Boundary last year.

Improvements made at the Granby Company's smelting works at Grand Forks were extensive, these including the construction of additional ore and coke storage bunkers of a capacity, respectively, of 7000 and 4000 tons; a steel dust chamber at the back of the blast furnaces to replace the brick chamber formerly used; enlargement of the brick dust settling chamber near the smoke stack; substitution of a steel and brick building of larger size, and having cement floors, for the old wood structure used as a blowing-engine room; installation of two Cornersville rotary blowers, each 30,000 cu.ft. per min. capacity and each having two 150-h.p. induction motors; lengthening of the copper-converter department, preparatory to installing three 7x10 ft. 6-in. converters to have a total capacity of 36,000,000 lb. of copper a year and to be electrically operated, in place of those heretofore in use; installation of a two-cylinder 40x40x42-in. Nordberg blowing engine of latest type, capacity 10,000 cu.ft. per min. at 12 lb. pressure, and driven by electric power; and numerous improvements to electric plant, water-supply service, etc. The lengthening of the eight 18-ft.x44-in. blast furnaces to 22 ft. each has been commenced, and when this work has been completed, probably by June next, the treatment capacity of the works will be 4000 tons of ore per day instead of 3000 tons, as at present. The total quantity of ore treated at these works in 1908 was 1,037,000 tons, and the copper produced amounted to 23,535,000 lb., which is the largest production yet made here in any one year.

No important new construction work was done at the Granby mines in 1908, they having been previously equipped for a daily production up to 5000 tons of ore. On an adjoining group of claims the Consolidated Company opened up what promises to prove to be a large body of ore of workable grade. The B. C. Copper Company doubled the air compressor capacity at its Mother Lode mine, installing a Canadian Rand 35-drill engine, electrically driven by a 700-h.p. induction motor and a rope drive. At its Oro Denoro mine the same company installed an ore-crushing and conveying plant, and a plant for similar purposes at its smelter sampling works at Greenwood. Numerous less important improvements and installations were also made at its several mines and its smelting works. Recently the company issued a circular showing that during six months ended Nov. 30, last, it had produced about 5,548,000 lb. of copper which, together

with the gold and silver also recovered, was of a total value at the time of shipment of \$1,038,085, and from which there would be a total profit estimated at \$226,700.

Rossland mines are estimated to have produced a total of 5,300,000 lb. of copper in 1908, in the following proportions: Centre Star, 2,666,000 lb.; Le Roi, 1,705,000; and Le Roi No. 2, 928,000 lb. The ores of all these mines contain gold and silver as well as copper, Le Roi No. 2 being especially favored in recovering an average gold value fully twice that from the other mines. Extensive developments and, at the Centre Star, substantial improvements as well, were made at the mines, but particulars were not supplied, except that the Le Roi expended \$108,000 in development work consisting of 6000 ft. of drifting, raising, crosscutting, etc., and between 4000 and 5000 ft. of diamond drilling. The most important results achieved during the year were the finding of bodies of ore of good grade in the deeper levels of all three mines, in the Le Roi on the 1650-ft. level, in the Centre Star down to about 2000 ft. on the incline, and in the Le Roi No. 2 on the 700-ft. level, and deeper in a diamond-drill bore.

In the Coast district the copper production to be noted is that of the Marble Bay mine, Texada island, which shipped 10,000 to 13,000 tons of ore containing up to 5 per cent. copper; of the Britannia Mining and Smelting Company, which last June resumed operations on a small scale at the Britannia mine, Howe sound, and shipped to the smelter about 10,800 tons of ore and concentrate, containing approximately 646,000 lb. of copper, besides gold and silver; of the Tyee Copper Company, which shipped several thousand tons of good-grade ore from the Indian Chief group on the west coast of Vancouver island; and the Awaya, Ikeda Company, which sent to the Tyee smelter from its mine on one of the Queen Charlotte islands about 5400 tons of ore containing about 500,000 lb. of copper and fair amounts of gold and silver as well. The Hidden Creek Mining Company opened up a very large body of ore on Observatory inlet, Portland canal, along a distance of about 2000 ft., ranging in copper from 2 to 10 per cent. but did not ship any to the smelter.

The Britannia company's copper-smelting works on Vancouver island were not operated in 1908. At the Tyee Copper Company's smelter, Ladysmith, Vancouver island, many improvements were made. A wharf was constructed in Oyster Harbor and a trestle built to connect with the smelting works. On the wharf ore bunkers provided with mechanical equipment for expeditiously unloading ore from vessels, were built, and machinery, both steam and electric, was installed to facilitate handling the ore. All plant and machinery requisite for doub-

ling the treatment capacity of the works was purchased and received before the year closed.

ZINC AND IRON

Although the zinc smelter built at Frank, Alberta, has not yet been made suitable for smelting zinc ores, there has been in British Columbia in 1908 some production of zinc concentrate, to an extent of between 9000 and 10,000 tons. About 8000 tons were shipped from the Whitewater and Whitewater Deep mines, of which 3000 tons had been held over from 1907 and the remainder made in 1908. This product averaged about 44 or 45 per cent. zinc and also carried silver. The Ruth mine at Sandon, Slocan, sent to Kaslo, nearly 1000 tons of zinc concentrate, the grade of which was raised to about 50 per cent. zinc at the Kootenay Ore Company's sampling works and 250 tons of the product shipped, leaving about 650 tons on hand. The Vancouver mine shipped 1036 tons of concentrate averaging 45 per cent. zinc and 40 oz. silver per ton. The remaining production was in smaller lots.

The works built at Nelson for the treatment of lead-zinc ores by the Snyder electric process were in successful operation during the closing weeks of the year. It is claimed that metallurgically the process is distinctly successful, but that mechanical difficulties occasionally occur, the overcoming of which will be a matter of time and experience in the practical working of the plant.

Last summer a laboratory Elmore vacuum plant was taken to the Hewitt mine, Slocan, where tests were continued over two weeks. Experiments in cleaning iron out of the concentrate, instead of using a magnetic separation process were successful on a concentrate carrying about 40 oz. silver per ton, 20 per cent. zinc and 18 per cent. iron in the form of siderite. The Elmore process made a concentrate of 48 to 50 per cent. zinc, and carrying 80 to 120 oz. of silver per ton. The proportion of iron left in the concentrate was only 6 per cent. The extraction was from 88 up to 96 per cent. of zinc from the original feed, and the silver extraction was equally good.

At the Blue Bell concentrating mill the zinc-separation plant is not yet in full operation. The ore here contains about 30 per cent. pyrrhotite which, with the zinc blende also in the ore, leaves the Willey tables and finer jigs and, after dewatering, is conveyed to a drying furnace, cooled, and elevated to a magnetic separator. It is expected to make a product of 40 to 45 per cent. zinc, but while the price of spelter continues low experiments with the plant will be extended over a longer period than might otherwise be deemed profitable.

Iron mining is practically non-existent

in the province at the present time. The product of iron in 1908 was of absolutely no importance. The full report of Einar Lindeman, who in 1907 was sent to the British Columbia coast by the Dominion Department of Mines to examine occurrences of iron ore is being awaited. Meanwhile there is no production of this metal, even from properties which in past years have made shipments to a small iron furnace on Puget sound.

COAL AND COKE

The year's net production of about 1,700,000 long tons, which was less by 100,067 tons than that of 1907, was chiefly from Vancouver island collieries, of which the Wellington Colliery Company produced about 740,000 tons, and the Western Fuel Company 393,000 tons. On the mainland of the province, the Crow's Nest Coal Company produced 522,000 tons and the Nicola Valley Coal and Coke Company, with recently opened mines in the Nicola district, about 30,000 tons. Coke production was 13,000 tons at the Wellington Colliery Company's ovens at Union, Vancouver island, and 235,000 tons at the Crow's Nest Pass Company's ovens at Fernie and Michel. Among a number of substantial improvements and additions to equipment the latter company is making is the installation of the Greene superposed track system self-dumping car haul at its Michel colliery to eventually have a capacity for handling 6000 tons of coal daily. A Canadian Rand four-stage, high-pressure air compressor, having a capacity of 3000 cu. ft. of free air per min., is also being put in at this colliery. It is noteworthy that the larger companies mining coal in the Crow's Nest Pass region are substituting the most economical type of Corliss condensing engines for the simple slide-valve engine with its excessive steam consumption.

On December 18, the Hosmer Mines, Ltd., commenced the shipment of coal from its newly opened colliery at Hosmer, on the Crow's Nest branch of the Canadian Pacific Railway. This company's property consists of six sections of coal lands and two sections of surface, on which the town of Hosmer, and improvements connected with the colliery plant are located. There are 13 coal seams on the property varying in thickness from 4 to 30 ft. The mine buildings, tipples, trackage, machinery and plant for ventilation, haulage, power, and all other requisite purposes, are extensive, modern and complete, and everything about the colliery is planned with the object of developing here a large and important coal-mining and coke-making industry. Beehive coke ovens, 240 in number, have been erected, sufficient to give an initial output of about 300 tons per day, while the putting in of Belgian ovens, with by-

product recovery, and distilling plant, are included in the plans for the future. Additional ovens will be built as required. This enterprise has been established under the immediate supervision of Lewis Stockett, who was also associated with the Bankhead colliery, at Banff, Alberta, which, like the Hosmer mines, is an industry connected with the Canadian Pacific Railway Company.

Another coal-mining industry established last year 'is that of the Corbin Coal Company, which has lately opened a mine in the Crow's Nest district and connected it by a 17-mile railway with the Canadian Pacific Company's Crow's Nest branch. In addition there are several other coal companies which are preparing for mining coal but they are not yet in a position to regularly maintain an output.

The South Wellington Coal Mines, Ltd., has opened a coal mine on Vancouver island and, during the course of development work has taken out about 15,000 tons of coal. It is now installing a tiple of 1000 tons daily capacity, constructing a tramway seven miles to tide water, and building bunkers and a loading plant at the shipping point. This company expects to have its preparatory work completed by next May.

Seward Peninsula in 1908

By JOHN POWER HUTCHINS*

The gold production of Seward Peninsula, of which Nome is the largest town, was about \$5,000,000. The following tabulation shows the gold production since 1900.

GOLD PRODUCTION OF SEWARD PENINSULA.

1900	\$4,000,000
1901	4,500,000
1902	5,050,000
1903	4,437,000
1904	4,875,000
1905	4,600,000
1906	7,000,000
1907	6,500,000
1908 (estimated) ..	5,000,000

The summer of 1908 was very dry and this caused reduced output. The freeze-up came about September 20 and was earlier than usual. The placers of Seward Peninsula are scattered over a considerable area and discoveries and developments will continue for several years with an annual increase in gold production in normal years.

Discoveries and developments of importance were made on the old beach lines back of Nome, and it is entirely probable that these will continue for a number of years. Considerable gravel containing as much as \$100 per cu. yd. was extracted.

There were no labor difficulties in 1907, and the supply of men was ample at all times. Wages are high, 40c. per

hour and board, and 30c. per hour and board, being the respective rates for skilled and unskilled labor. Open-cut mining with hand methods begins about June 15, and continues until about October.

The amount of gold produced by drift mining was a greater proportion of the whole than in normal years. This kind of mining is not seriously affected by drought. Probably more than two-thirds of all the gold was produced by this method. It is applied almost exclusively at present for mining the old beach lines back of Nome.

THE OLD BEACHES

These old beaches are interesting for both economic and geologic reasons. They are probably areas where gold-bearing material transported by streams was concentrated by wave action during considerable periods of stability, the region back of Nome being successively elevated. There are several of these beaches and the material in the areas between them is, also said to be gold-bearing.

It is locally believed that the old beaches and the intervening areas will be worked by floating dredges. Much of the ground is frozen, and as yet it is uncertain whether it can be thawed cheaply enough to allow of operating with profit. Considerable has been written of frozen ground during the last year, and it is considered by some to be merely a "bugaboo."

DREDGING

Gold dredging was carried on about as usual. A new dredge with 9-cu.ft. buckets began operations, and after numerous accidents sank; it is now a wreck. Bad design, construction, and management combined with difficult conditions to produce this result. Similar terms may be applied to almost every other dredge that has been installed on Seward Peninsula. In South America the same proportion of disasters prevails. Many of the failures occurred where there probably is considerable gold.

HYDRAULIC MINING

Hydraulic mining suffered most by reason of the dry weather. Some of the large ditches were practically dry during more than half of the working season. The summer was one of the driest ever known.

There is not much open-cut mining with hand labor on Seward Peninsula. The water supply is generally better than that of the interior of Alaska and some form of hydraulic mining can generally be applied. There are stream beds that can not be mined by open cutting with hand labor because of unfrozen ground which results in a heavy inflow of water; the streams are generally of considerable size, and are, therefore, difficult to turn from their beds and to control during freshets.

The Milling Situation at Cripple Creek

SPECIAL CORRESPONDENCE

Immediately after the Golden Cycle mill went into active operation, the Mill Trust withdrew the excessive treatment rates to conform to the more moderate prices charged by the Golden Cycle for the treatment of Cripple Creek ores. The shippers of the district had, however, considered themselves long-suffering under the exactions of the Trust, and at anything like equal rates favored the competitive mill. The Mill Trust then established an open rate, effective also on all existing contracts, through which the treatment rates were reduced \$1@2 per ton, and a low mark of \$3.50 was established for the treatment of ores below \$8 valuation.

Things then proceeded mildly for a period of about six months, the papers of the district being rendered somewhat lively and humorous by the facetious advertisements of the rival mills. The next move in the game was the restoration of the old rate by the Mill Trust on Oct. 15. This brought no response from the Golden Cycle people, but the amenities and frivolities in the advertisements in the local papers gradually disappeared, and the shrewd miner became suspicious of an understanding being arrived at between the two.

Now comes a feeler from the Golden Cycle company, in which the general manager intimates that the stockholders at the coming meeting of the company may decide to raise the treatment charges, inasmuch as the mill has now been in operation for something over a year, and the officers of the company, having obtained their experience in the only practical school, have at last ascertained the cost of treating a ton of Cripple Creek ore.

In this connection we call attention to the speech of the president of the Golden Cycle Mining Company at the banquet of last year, in which he stated that he knew the tailings loss was about 80c. per ton, and the cost of working a ton of ore a trifle over double that amount. Meanwhile the Mill Trust, having obtained its second wind, since the late advance in treatment charges, has announced as a Christmas offering to the mineowners a reduction in treatment charges on low-grade ore effective Dec. 26. The new rates are: On ore up to 0.5 oz., freight and treatment, \$4.50—old rate, \$5.25; to 0.75 oz., \$5.25—old, \$6.50; 1 oz., \$6—old, \$6.75 per ton.

Silver and copper amalgamation plates, according to Henry Louis, should be coated with silver amalgam until each square foot contains $\frac{1}{4}$ oz. of silver; W. A. Caldecott states that much less silver can be used with good results.

Methods of Mining the Granby Orebodies

The Large Uniform Deposits Require Little Timbering, and Electric Power Is Used for Haulage and Operating Air Compressors and Pumps

BY C. M. CAMPBELL*

The Granby company is at present operating in Phoenix what appears to be two distinct groups of orebodies. The oldest workings are in the deposits which outcrop on the Knob Hill and Old Ironsides claims, while the later workings are about half a mile to the east and are almost entirely on the Gold Drop claim. The Knob Hill-Ironsides deposit has been opened up, at 100-ft. intervals, by several levels. The upper one of these, No. 1 tunnel, was originally a shipping level and from the stopes above this level and from

3 tunnel. The No. 3 tunnel equipment handles all the ore between this level and No. 2 tunnel and its terminals are on the Great Northern railway. In descending order the remaining main levels are known as the 200-ft., 300-ft. and 400-ft., and the tonnage from all these levels is hoisted through the Victoria shaft. The bins connected with this shaft are served by both the Canadian Pacific and Great Northern railways. The Knob Hill-Ironsides mine is thus divided into three distinct units known as No. 2 tunnel, No.

largely the result of evolution. The first few years of work showed that the ore was of decidedly low grade. On the other hand it also showed the orebodies to be of vast size with value uniformly distributed. The nature of the ground was also found to be such that timbering could be almost dispensed with. As a result of this, sorting was abandoned; the square set method gave place to open stopes with the roof supported by rock pillars; cheap electric power was introduced to operate air compressors, for pumping and for haulage;

TRANSVERSE VERTICAL SECTION THROUGH THE OREBODY. THE AREA SHOWN IN BLACK IS BLOCKED IN 100-FT. SQUARES

the open cuts in which a steam shovel worked, nearly a million tons have been shipped. When the crusher at the mouth of this tunnel was destroyed by fire, it was rebuilt at the mouth of the next lower level known as No. 2 tunnel. No. 1 tunnel then became nothing more than an intermediate level, all the ore above No. 2 tunnel being handled through that outlet.

After being crushed this ore falls directly into Canadian Pacific railroad cars, or if none are at hand it is diverted into a pocket which is reached by a cross-cut from the next lower level known as No.

3 tunnel, and Victoria shaft. These have a distinct and complete equipment of rolling stock, crushers and bins and are manned by separate crews under separate shift bosses.

The Gold Drop is equipped like the others and forms a fourth unit. The output from this mine is handled by the Canadian Pacific. In case one railway is unable to operate, the shipments from at least three outlets can be handled by the other road. Also, if one or more of the units happen to be out of commission, each of the others can be pushed toward its maximum capacity of 150 tons per hour and the day's shipment made up.

The methods of underground mining are

cars up to 10 tons capacity and running on a 3-ft. gage took the place of the small mine cars previously in use, and, as stated above, the different outlets were equipped with up-to-date shipping facilities. All these improvements have had the end in view of giving the mine a large, uninterrupted, daily tonnage.

NATURE OF THE DEPOSIT

A transverse vertical section taken about the middle of the orebody is shown in an accompanying illustration. At this point it shows up to, perhaps, the best advantage. The section shows two orebodies. As a rule the area between these orebodies is absolutely barren. Some drill holes, how-

*Mining engineer, Phoenix, British Columbia.

NOTE.—From advance sheets of the *Journal*, Can. Min. Inst., Vol. XI.

ever, have shown it to contain a few tenths in copper and in this section part of the area is mineralized sufficiently to place it in the shipping class. At the place where this section is taken a crosscut could be started in ore at the footwall and driven more than 600 ft. before again encountering waste rock.

The orebody is cut by several faults. The only one which seems to throw the orebody to any extent is shown in the section. This has been traced from one end of the deposit to the other and shows a throw of from nothing to one hundred feet. This fault plane dips to the west at an angle of about 55 deg. Several other fault planes occur dipping at various angles to the east, but none of these affect the continuity of the ore. In some cases they apparently do so. This is due to the fact that the strike and dip of these slips are much the same as those of the orebody, and when a slip occurs close to the hanging wall of the deposit it may act as such for a hundred or two hundred feet. Beyond this the mineralization will either

round are then blasted, and as these throw the rock to the sides of the raise the timbers of the chute are uninjured. The raise is then carried ahead at an angle of about 45 deg. This allows the muck to run and also enables the men to get about without the aid of timbering.

For ventilation purposes the first raise of a series is usually carried through to the level above or some other convenient opening. In the case of the highest level the most convenient opening is the surface. When the face of No. 2 raise is about 30 ft. above the sill floor, stoping is commenced and it is widened out until it connects with No. 1 raise. The same thing is done at an elevation of about 60 ft. In this way the raises are carried ahead, connecting with each other at heights of 30 ft. and 60 ft., and breaking through into the next level at 100 ft. The only small work is in the first 30 ft. This is charged to development, the remaining excavations being placed in the stoping account. In this way a network of pillars is left throughout the stope. So far a

is steeper. It is often advisable when breaking a raise through from a lower level to make the connection at the back of the chute timbers. The timbers can be taken out and a glory hole started. At the same time the raise can be carried ahead as a stope 10 to 15 ft. beneath the foot of the old stope. While stoping ahead, upper holes are drilled into the undercut rock. In this way the back is always within reach. In fact it is rarely necessary to work in a stope at any great distance from the roof.

When raising in waste no connections are made until the ore is reached. If the ore is at any considerable distance the raises are put in less frequently and are branched so as to tap the ore at two or three places. After the ore is blasted the large blocks that can be reached are bulldozed. No blockholing is attempted. It has been found cheaper to buy more powder than bother with hand or air-hammer drilling. When the raises are in ore, there are always convenient temporarily abandoned chutes, which have been

MARCH, 1905

MAP OF STOPES BETWEEN NO. 2 AND NO. 3 TUNNEL LEVELS

MARCH, 1908

break through and ore be found on each side of the slip or it will fall away from the slip and waste will replace the ore. When a clean slip occurs as a hanging wall, few pillars are needed and a large stope can be made with a safe roof. In most parts of the mine the division between ore and waste is more gradual. Sometimes it may be a few inches; it is seldom more than a few feet and can usually be recognized without any sampling.

SCHEME OF OPERATIONS

In opening up a level, parallel drifts, usually about 75 ft. apart, are started in the direction of the strike of the deposit. At intervals of about 45 ft. along the drifts raises are begun. An 18-hole round is drilled and blasted. Before the muck is cleared away the bar is again set up and another round drilled and blasted. The third round is then drilled, but the cut holes only are blasted. All the rock is then shoveled up and the chute is built. The remaining holes of the last

column only has been used. As soon as the sill floor above has been reached, tripods and long steel can be used to advantage. In this way a glory hole is started and the opening can be widened out until the sides of the glory hole get too flat for the ore to run. Machines are also put to work where the connections between the raises have been made and at other advantageous places. The stope may thus be turned back to meet the hanging wall and the pillars reduced in size, or where the nature of the ground permits, a pillar may be eliminated altogether.

One series of raises is seldom sufficient to tap all the ore. If the footwall is flat, a parallel drift in waste with accompanying raises will have to be driven. There will also be several drifts between the foot and the hanging wall. At one place on No. 3-tunnel level there are five parallel drifts now operating and at least another will be required. In this case the pillars in the stopes are left nearly vertical instead of at an angle as when the deposit

cleaned out, through which access is had to the broken ore in the raises. In the case of raises through waste, where no connections have previously been made, it is necessary to drive manways. To do this a staging is constructed midway between two chutes and about 8 ft. above the track, high enough to allow the trolley wire to pass under. The planks at the center of the staging, over the cars, are movable. A miner with an air-hammer drill or a small, ordinary drill starts a raise at about 60 deg. and continues for about 25 ft., when he branches and drifts until he connects with the raises on each side. The waste with a little help is run into the cars without interfering with traffic.

CHUTES AND TIMBERING

The abandonment of timbering in the stopes has already been referred to. The only other timbering required is for chutes, tunnel sets and occasional posts and caps on the sill floor where needed.

The details of a chute are shown in an accompanying illustration. In building this a temporary staging is constructed, hitches are cut for the posts, a sprag is wedged between the hanging and foot-wall of the raise, a block and tackle attached thereto and the stulls raised and wedged in position. The stulls are then lagged up inside. A space is left unlagged for the chute proper, and at the sides of this space and inside are placed posts surmounted by a heavy cap. The chute is built in, the gate placed in position, a permanent platform built for the chutemen and the work is completed. The chute opening is about 3 ft. square, and anything that can go through the chute can go through the cars and be handled by the crusher.

When the muck is drawn through the chute from the raise the lagging and inside posts are pretty well protected by broken rock. The cap, however, suffers

This is the usual experience. In No. 3 tunnel there is a double-tracked stretch of 900 ft. of which 300 ft. is timbered with sets and top lagging.

SILL FLOOR WORK

On the sill floors the haulage tunnels are always being driven ahead. On the levels where the big cars run these are about 9x11 ft. in size. For a drift of this size a 20-hole round is used. This is made up of four lifters, four cuts, eight breast holes in two rows and four back holes. All the rock broken on the sill floor is hand shoveled. For handling the ore different types of cars are in use. On the No. 3-tunnel level 10-ton, steel, hopper-bottom, and 7-ton, wooden, gable bottom cars are operated. These run on a 3-ft. gage and are operated by an electric locomotive. Owing to the 6-ft. height of the steel cars, they could not be used for shoveling into from the sill floor and for this reason the

hands of a mucker boss who is responsible to a shift boss and who oversees the shovelers and chutemen. A chuteman, working with a helper, loads the ore from the chutes. In case a chute gets blocked he does the blasting necessary to clear it. The train crew consists of a motorman and a head and back brakeman. The head brakeman is in charge of the train and does whatever is necessary in the cars.

On the No. 2 tunnel level the working and equipment is practically the same except that a steam locomotive takes the place of the electric one.

In order to overcome the defects of the cars in use and those available, a special steel car was designed at the works. This is used on the 400-ft. level. This car, shown in section in an accompanying illustration is 5 ft. high and can be used for sill-floor shoveling as well as for loading from the chutes. The box has a 5-ton ca-

CONSTRUCTION OF CHUTE

more or less from blasting and in course of time is replaced if necessary. If convenient, heavy railroad iron covered with lagging may be used instead of a wooden cap. Chutes have been built lined with tank plates, and the inside timbers armored. This, however, is seldom done, as the life of an ordinary chute is usually long enough to handle all the ore from that part of the stope of which it is the outlet.

The chute gate is a solid piece of sheet iron, and is operated by a lever. It is shown in section in the drawing of a chute. In case a car is loaded and the gate is prevented from closing by a large rock, a plank or two is moved along the staging against the mouth of the chute thus preventing any loose rock from running over. Tunnel sets are rarely needed. The main haulage way on the 40-ft. level, a straight run of about 1000 ft., has no timbers other than those necessary to carry the electric light and trolley wires.

SKIP-LOADING DEVICE AT VICTORIA SHAFT POCKETS

lower wooden cars were built. They are not adapted for loading from chutes as on account of their low height the muck is liable to shoot over. In order to deliver the large tonnage required of this level these cars were an absolute necessity. There are 15 of the steel ones and five wooden ones on this level, and since their introduction three years ago they have handled close to a million tons of coarse ore besides a large amount of waste. They are all still in use and in good working condition. They have, however, their defects. The steel cars are a little too long to receive a full load without being moved. The bottom gates do not always close tightly, and men have to be kept shoveling off the track. In unloading, the large rocks often arch over in the car and when they cannot be dislodged with a pinch bar, dynamite has to be used. As this is hard on the rolling stock there is usually a car or two in the repair shop.

Underground the ore loading is in the

capacity, and has an automatic side-dumping arrangement. When a train comes to the unloading pocket, the motor goes ahead with slackened speed and a side wheel attached to the box runs up an inclined plane, the box tips, dumps its load and closes again. Since its installation in January, 1908, this arrangement has given excellent satisfaction.

At the Gold Drop mine the entire output is dropped down a raise 300 ft. long to the Curlew tunnel. From the chutes at the bottom of the raise to the crusher bins, a distance of 800 ft. the ore is hauled in 3-ton, side-dump, wooden cars by an electric locomotive. An air lift is used to dump the cars.

THE VICTORIA SHAFT

The lower levels were originally worked by shafts Nos. 1 and 2. These were vertical, of small size and capacity and were worked to their limit. Besides, they were not centrally located for future workings.

In order materially to increase the output from below, the Victoria Shaft was constructed in 1905. This shaft cuts the upper orebody where that deposit crosses the 400-ft. level. The shaft is on a 60-deg. incline and connects with large storage pockets below the 400-ft. level. These pockets, ore and waste, are connected with the 300-ft. level by raises, thus materially increasing their capacity. The 200-ft. level will eventually be connected in the same way, or separate pockets may be cut out below that level.

The skip-loading device is shown in one of the illustrations. The finger gates shown in the drawing is supplemented by an extra gate made out of a piece of sheet iron. By this means the fines which would naturally slip through the fingers of the main gate are caught and prevented from going down the shaft. This type of finger gate, the sheet-iron attachment being omitted, is in general use at all crushers except that at No. 3 tunnel bins. In the case of the No. 3-tunnel crusher 48x-in.

timbermen's helpers, 46 chutemen, 84 muckers and chutemen's helpers, 12 nippers, six blasters, 10 harmen, three trackmen, three trackmen's helpers, three pumpmen and pipemen, one ditcher, six motormen, two locomotive engineers, eight head brakemen, six back brakemen, two car repairers, two oilers and two skip tenders, a total of 387. During this month the shipments went slightly over 3000 tons per day.

DIAMOND DRILLING

Since starting operations more than 30,000 ft. of holes have been drilled. Almost all of this has been of small size and no holes have been deeper than 600 ft. All work is done by contract, the company furnishing power and water. The mineralized portion of the core is sampled and the results are found to agree remarkably well with those of the orebody when opened up. From several holes the cuttings were collected every few feet and analyzed. As the values were away high.

found necessary to keep a considerable number of maps on file. A general map showing the bulk of the company's land, buildings and underground workings is made to a scale of 100 ft. to the inch. Combined sill-floor plans on a scale of 40 ft. to the inch are made of the Knob Hill-Ironsidles and Gold Drop mines. Brownprint copies of these are placed in the shift bosses' offices. It has also been found necessary to keep the stopes above each level on a separate map and separate maps are made of each level showing the geological features, especially the ore boundaries.

Transverse vertical sections are made every 200 ft. These last two series of maps are used in calculating the ore in sight. The permanent features such as shafts, side lines, drill holes, etc., are put on in ink, but as the geography of a level changes so rapidly the rest of the workings are indicated in lead pencil. From all these maps a set of brownprints is made at intervals. From the sill-floor plans a

ARRANGEMENT OF GATES AT VICTORIA CRUSHERS

square steel bars running in guides and worked by an air lift are used as shown. These do as good work as the finger gates, but no better, while they need more head room to install and have a greater initial cost.

A classification of the underground force employed at two different periods will show the expansion and development along new lines of the company's operations. The figures refer to the Knob Hill-Ironsidles mine only, the Gold Drop being left out of consideration. In March, 1902, the average 24-hour crew consisted of one foreman, five shift bosses, one timber boss, 92 miners, 26 timbermen, 139 muckers, one pumpman, four nippers, two trackmen, two samplers, four blasters and two cage tenders. This makes a total of 280 and during this time the shipments averaged about 1000 tons per day. In March, 1908, this crew was made up as follows: One day foreman, one night foreman, seven shift bosses, one timber boss, six mucker bosses, 160 miners, nine timbermen, six

timbermen's helpers, 46 chutemen, 84 muckers and chutemen's helpers, 12 nippers, six blasters, 10 harmen, three trackmen, three trackmen's helpers, three pumpmen and pipemen, one ditcher, six motormen, two locomotive engineers, eight head brakemen, six back brakemen, two car repairers, two oilers and two skip tenders, a total of 387. During this month the shipments went slightly over 3000 tons per day.

SURVEYING AND MAPPING

When the conditions are the same the surveying operations are, I think, much like those in other British Columbian mines. The coordinates of all important stations are kept on different sheets in book and ledgers. Depending on the importance of a piece of work the notes may be plotted by coordinates, by tangents or with a small protractor. It has been

glass model of the Knob Hill-Ironsidles is kept up to date. This consists of sheets of glass running in slides in a plate-glass frame. On the glass sheets are outlined the different levels, areas of the orebodies, faults, etc., and as the space between the glasses corresponds to the space between the levels a better idea of the ground can be obtained than when all the plans are in the one plane. This arrangement does not need to be referred to often, but when it is needed it is found to be of very considerable help. It is the intention to supplement this with another similar arrangement having vertical glasses instead of horizontal ones. These will have the transverse vertical sections marked on them.

STOPE MAPS

The method of mining employed, whatever other advantages it may have, certainly does not tend toward simplicity in the stope maps. These are necessary to show the relation of the pillars to the

level below and the level above. The vertical sections are also constructed from these maps. As the stopes consist of a series of raises and glory holes with all the intermediate stages and with the pillars standing at different angles due to different dips of the orebody, it is not a simple matter to make a map which will show all these features to advantage. After considerable experiment it was decided to adopt, and adapt somewhat, what is known as the "hachure" method of map construction as used in topography. As the appearance of a stope soon changes, no attempt is made to go into unnecessary detail. In surveying, a setup is made in as commanding a position as possible, sights are taken to the governing points on the pillars and the ridges between the glory holes. These points are plotted and when the tracing is made, contour lines, afterward erased, are drawn in pencil on the tracing, approximately at 10-ft. intervals. The hachure lines are then inked in, their extremities being at right angles to the adjacent contour lines. Thus when the contour lines are not parallel the hachuring has a radiating appearance. When it is advisable to know the exact height of any part of a stope the elevation above sea level is marked on the map at that place.

Ore in sight, ore developed, ore blocked out, or whatever term may be preferred, is calculated independently from the sill-floor plans and from the transverse vertical sections. The mean of these estimates, which do not vary to any considerable extent, is then taken. The horizontal area of each orebody as it crosses a level has been pretty well defined by drifts, cross-cuts and drill holes. The average of this area and the area on the level above is multiplied by the vertical distance and from this product the tonnage is calculated. Each block of ground is figured out separately, and from the total the ore shipped is deducted, the balance being ore in sight. The ore extracted between shipping levels is also kept track of and the ore in sight in different blocks of ground can thus be estimated.

BROWNPRINTS

As a number of technical men who have visited us during the last few years have found this process to be a novelty, a few remarks regarding it may be excusable. The process is used chiefly for the reproduction of mine maps, blueprints being used for mechanical drawings. A tracing is first made from which a negative on thin, brownprint paper is obtained. Using paper of a heavier grade a positive consisting of very dark brown, practically black, lines on white background is produced. The different levels, which are superimposed in part, can then be colored and the map rendered intelligible to others besides the draftsman. There are also other advantages. When a tracing has to be brought up to date it

may happen that some pillars have been removed, drifts widened, etc. No erasures are made on the linen, but the extra lines needed are inked in and the lines not needed are simply inked out on the negative.

Another advantage is that the title, and other important lettering, has only to be made once and traced once. On subsequent tracings it is omitted. The original negative is, however, kept, and in future negatives it is only necessary to cut a hole where required and attach the negative of the title or whatever it has not been advisable to alter. There are other

SECTION OF MINE CAR, 400-FT. LEVEL

minor advantages which will show themselves after the process has been used for a little while.

The National Engineering School of Mexico *

By ARTHUR R. TOWNSEND†

The National Engineering School of Mexico is the foremost institution of its kind in the country. It is supported by the Government, the cost of maintenance and operation being, in 1896, \$72,041 Mexican money. It is the oldest mining institution on this continent, having been founded in 1792, by royal decree in response to a petition of the miners' guild, that part of the tax levied on silver bullion might be applied to this purpose.

It is housed in a building completed in 1813, which is larger than the school demands, being 290x265 ft. The Government employs the unoccupied portions for official purposes. Originally intended as a school for miners, its scope has been enlarged to include all the branches of engineering as well as architecture. The school has influenced the industrial progress of Mexico since its enlargement, and there are several features in which it differs from, yet compares favorably with, our similar institutions.

*Abstract of an article by Mansfield Merriman in the *Engineering News* of Sept. 19.

†114 Liberty street, New York City.

Since 1792 the total number of graduates is 522; of late years, the average has been 14 per year. By graduates are meant only those to whom diplomas are granted. This is conditional in most courses on the performance of a year's practical work in the engineering profession of the course followed. The requirements for entrance are the courses of the national preparatory school. The courses taught in the National Engineering School are mining engineering, civil engineering, geographic engineering, electrical engineering, topography, hydrography and metallurgy, the time varying from five years' instruction for mining engineering to one and one-half years' instruction in metallurgy. The tuition is free and anyone complying with the scholastic requirements can enter the school.

The work is well systematized, and the records of attendance and scholarship are thorough. The studies pursued are like those of our technical schools, save that ours are more broad and thorough. Of the textbooks used, but four are in Spanish, eight being in French and 12 in English. The recitations partake of the nature of discussions in which the instructors join. Of the students enrolled, many are disqualified from entering the examinations; of those that do, only 80 per cent. pass, which is about 45 per cent. of those enrolled.

The school is well equipped in instruments for surveying and for testing materials, but poorly so in regard to physics. Its weakest feature is the pay of the faculty. This is very small, and the members of the faculty are all engaged in other occupations and give up to the school only the few hours a week required for the recitations. From this there is lacking the influence of the older men on the students, one of the best features of our smaller schools. The students are not distinctive or organized as a body in the way that is so common here. There is none of the effort on the part of the faculty to push a backward student, watch over him and see that he graduates, as is done here. It is the reverse condition from ours. With us only the most stupid fail; with them only the bright ones succeed. This accounts for the small number of graduates and insures their being of a relatively higher standard than in our schools.

The director who is the head of the school, his assistants and all the professors are appointed by the president of the republic. All the professors must be Mexican citizens and graduates of the courses in which they instruct. Graduates of foreign institutions can obtain the degree by passing the examinations of the school; without it, no responsible position can be held on work conducted by the Government.

The Rare Metals VIII—Uranium

By CHARLES BASKERVILLE*

Uranium minerals occur most frequently in granites and pegmatites. The metal uranium is much less abundantly diffused than vanadium; however, it is found in a large number of rare minerals, many of which are of secondary origin.

URANIUM MINERALS.

	Oxide Content.
Uraninite, a uranate of uranyl, lead, etc.	75-85% UO_2 and UO_3
Gummite, an alteration-product of uraninite.	61-75% UO_2
Thorogummite, a hydrous thoriferous gummite.	22% UO_3
Yttrougummite, probably decomposed cleveite.	
Uranosphaerite, hydrous bisulphate of uranyl.	50% UO_3
Autunite, a hydrous phosphate of uranium and calcium.	55-62% UO_3
Torbernite, a hydrous phosphate of uranium and copper.	56-62% UO_3
Zeunerite, an arsenate of copper and uranium.	56% UO_3
Uranosphenite, an arsenate of uranium and calcium.	59% UO_3
Uranocerite, a phosphate of barium and uranium.	57% UO_3
Phosphuranylate, hydrous uranium phosphate.	71-78% UO_3
Trögerite, a hydrous uranium arsenate.	64% UO_3
Walpurgite, a basic arsenate of bisulphate and uranium.	20% UO_3
Uranopilite, a hydrous calcium uranium sulphate.	77% UO_3
Uranocalcite, an uncertain uranium sulphate.	36% U_2O_5
Medjdit, a hydrous uranium calcium sulphate.	
Zippelite, a basic uranium sulphate and calcium.	13-17 U_2O_5
Voglianite, a basic uranium sulphate.	12% U_2O_5
Uranocite, an uncertain uranium sulphate.	66-71% U_2O_5
Johannite, a hydrous sulphate of uranium and copper.	67% UO_3
Mackintoshite, a hydrous silicate of uranium and thorium.	22% UO_3
Samaraskite, a tantalocolumbate of the cerium and yttrium metals.	10-14% UO_3
Nollite, a variety of samarskite.	14% UO_3
Vietingholite, a ferruginous variety of samarskite.	9% U_2O_5
Annerödite, a pyro-niobate of uranium and yttrium.	16% UO_3
Hedkvistite, a stannio-tantalate of yttrium, etc.	2-5% UO_3
Bröggerite, a variety of uraninite.	76-79% U_2O_5
Cleveite, a variety of uraninite.	66% U_2O_5
Uraninite, a variety of uraninite.	67% U_2O_5
Carnotite, a vanadate of uranium and potassium.	62-65% U_2O_5
Uranothallite, a hydrous calcium uranium carbonate.	35-37% UO_3
Liebigite, a hydrous calcium uranium carbonate.	38% UO_3
Voglite, a hydrous carbonate of uranium, calcium and copper.	37% UO_3
Schröckingerite, a hydrous oxycarbonate of uranium.	
Randite, a hydrous carbonate of calcium and uranium.	32% U_2O_5
Thorite, anhydrous thorium silicate.	
Rowlandite, a yttrium silicate.	1-10% U_2O_5
Uranophane, a hydrous silicate of uranium and calcium.	0.4% UO_3
Hatchettolite, a tantalio-niobate of uranium.	53-67% UO_3
Fergusonite, a metaniobate of yttrium, uranium, etc.	16% UO_3
Tyrite, a variety of fergusonite.	1-8% UO_3
Bragite, a variety of fergusonite.	
Kocheilite, a variety of fergusonite.	0.43% UO_3
Sipylite, a niobate of cerium, etc.	3% UO_3
Yttriothallite, a tantalio-niobate of yttrium, erbium, etc.	0.8-1.5% UO_3
Euxenite, a niobate and titanate of yttrium, etc.	4-12% UO_3
Polycrase, a niobate and titanate of yttrium, etc.	0.5-20% UO_3
Arrianite, a heterogeneous decomposition-product.	
Blomstrandite, a tantalio-niobate of uranium, etc.	23% UO_3
Xenotime, yttrium phosphate.	4% UO_3

*Professor of chemistry, College of the City of New York.

Note.—The analyses are given in the nomenclature of the chemists at the time they were made.

The important uranium minerals are uraninite, bröggerite, gummite, thorogummite, uranosphaerite, autunite, torbernite, samarskite, and carnotite. Uraninite, or pitchblende, and carnotite are uraniferous minerals of commercial importance.

Metallic uranium and its carbide are employed in metallurgy to improve the toughness, hardness, and elongation of steel and iron. Uranium steel is used for manufacturing gun metal, armor plate, etc. However, as a steel-hardening metal, uranium is subordinate to vanadium, chromium, nickel and tungsten. Uranium is now employed in the manufacture of incandescent gas mantles, where its presence is found to improve the properties of thorium, cerium and zirconium salts. Uranium oxide has the property of imparting to a glass a beautiful fluorescence of a greenish-yellow color, and a fine velvet-black to porcelain, when heated in the enameling fire. Uranium salts are also employed in the laboratory. Uranium carbide is utilized for manufacturing filaments in incandescent electric lamps. Uranium minerals are treated for the extraction of radium salts. A convenient test for uranium minerals is to place a piece upon the black or orange paper envelop in which photographic plates are kept. The sensitive side of the plate should be next the mineral. After remaining in a dark room several days, the plate will show an outline of the mineral.

URANINITE

Uraninite occurs in granite rocks and in metallic veins. It often contains the metals of the lanthanum and yttrium groups, calcium, and iron. The largest deposits in this country are in Connecticut, North Carolina, South Carolina, Llano county, Texas, Colorado, especially near Central City, and in the Black Hills, South Dakota. In Gilpin county, Colo., uraninite occurs with auriferous sulphide ores; it is exported to Germany. This is the same as "pitchblende," found in Austria, from which practically all the radium salts are extracted.

Uraninite is a black, massive mineral of botryoidal or granular structure. The structure is sometimes columnar or lamellar, and the appearance is usually greasy or pitch-like. It is a brittle mineral, and the color is of a black shade—grayish, greenish, brownish, or velvet-black. The hardness is 5.5, and the specific gravity is from 6.4-9.7. The streak is brownish black, grayish, or olive-green.

Before the blowpipe, uraninite is infusible, or only slightly rounded on the edges, and sometimes colors the flame green from copper present. With soda on charcoal it gives a coating of lead oxide, and sometimes the odor of arsenic. Reactions for sulphur and arsenic may be obtained in the open tube, etc. With borax and salt of phosphorus, uraninite gives a yellow bead in the oxidizing flame; this bead assumes a green color in the reducing

flame. It is soluble in nitric acid, forming a yellow liquid from which ammonia throws down a yellow precipitate. It is not attracted by the magnet.

The bead tests for uraninite are characteristic for uranium oxide, and the appearance and streak are important for distinguishing uraninite from similar species.

CLEVEITE AND NIVENITE

Cleveite and nivenite contain UO_2 in larger amount, and are characterized by containing 10 per cent. of the yttrium earths. Nivenite occurs massive, and its color is velvet-black. It is more soluble than any other varieties of uraninite, being completely decomposed by the action of dilute sulphuric acid at 100° in an hour. Nivenite is found in Llano county, Texas. Bröggerite occurs in octahedral crystals, having a specific gravity of 9.03.

GUMMITE

This mineral is fairly abundant in Mitchell county, North Carolina. It is found in rounded or flattened pieces, which resemble gum in appearance. The luster is greasy, and the color is reddish yellow to an orange- or hyacinth-red. The streak is yellow. Its hardness is 2.5-3, and the specific gravity is 3.9-4.2. Gummite is an alteration product of uraninite.

Before the blowpipe gummite yields much water and a bituminous odor. With salt of phosphorus in the oxidizing flame, it yields a yellow bead, which becomes green in the reducing flame, leaving an undissolved skeleton of silica.

THOROGUMMITE

Thorogummite occurs with fergusonite, cyltolite, etc., at the gadolinite locality in Llano county, Texas. It is found usually massive, but sometimes in groups of crystals resembling zircon in form. The hardness is 4-4.5, and the specific gravity is 4.43-4.54. Its color is dull yellowish brown, but after ignition, it becomes of a dull greenish hue.

Thorogummite is easily soluble in nitric acid, and responds to tests for uranium (see uraninite) and for thorium (see Thorium, thorite).

URANOSPHERITE

This mineral occurs with other uranium minerals near Schneeberg, Saxony. It is found in half-globular aggregated forms, having a dull or slightly lustrous surface. The luster is greasy, and the color is orange-yellow or brick-red. Its hardness is 2.3, and its specific gravity is 6.36. The streak is yellow.

Uranosphaerite decrepitates on heating, and a mass of crystalline needles results. These needles possess a silky luster and brown color.

AUTUNITE

Autunite is found in thin, tabular crys-

tals of a bright yellow color and pearly luster, and also in aggregates with a micaceous structure. It occurs in Connecticut, Massachusetts, Pennsylvania, North Carolina, South Carolina, South Dakota, and Utah. It is usually associated with albite, columbite, gneiss, or mica.

Autunite laminae are brittle, and the luster is pearly on the base. The hardness is 2-2.5, and the specific gravity is 3.05-3.19. Its color is lemon- to sulphur-yellow, and the streak is pale yellow.

Autunite fuses on charcoal to a black crystalline globule. With salt of phosphorus or borax, it yields a green bead in the reducing flame. With soda, a yellow, unfused slag results. The nitric acid solution is yellow.

TORBERNITE

This material occurs in thin, square tables of a bright green color and pearly luster. Sometimes it is found in the pyramidal or foliated, micaceous form. The hardness is 2-2.5, and the specific gravity is 3.5. It is brittle, and the streak is pale green.

Torbernite fuses easily before the blowpipe to a black mass and colors the flame green. With borax it gives a green glass in the oxidizing flame; this glass assumes a red color in the reducing flame. With salt of phosphorus it yields a green bead, which becomes red after being treated with tin on charcoal. With soda it gives a globule of metallic copper. The copper button is often whitened by arsenic. It is soluble in nitric acid, forming a yellowish green solution.

URANOPHANE

This mineral occurs in minute acicular crystals, and also in the massive form with a fibrous structure. The variety from Mitchell county, N. C., is a yellow colored mineral, having a hardness of 2-3, and a specific gravity of 3.834. The luster is vitreous.

Uranophane yields alkaline water in the matrass, and is rusty-brown colored on cooling. When heated in an open tube, it becomes almost orange colored. Before the blowpipe, it fuses to a black glass and colors the flame a slight green. With the fluxes it shows silica and uranium reactions. It dissolves in hydrochloric acid with the separation of silica in flakes.

OTHER URANIUM MINERALS

Phosphuranylite occurs as a pulverulent incrustation, having a pearly luster and yellow color, with other uranium minerals in Mitchell county, N. C. It yields water in a closed tube, and assumes a brownish yellow color on cooling. It is easily soluble in nitric acid.

Trögerite is found in thin, tabular crystals, having a pearly luster and lemon-yellow color, in the Black Hills, North Dakota. It is associated with uraninite. It yields considerable water in a closed tube and grows darker. It fuses easily, giving

a pale blue flame. On charcoal it gives an arsenic odor, and shows characteristic uranium reactions with the glass fluxes.

Randite occurs as a canary-yellow incrustation on granite near Philadelphia, Penn.

Samarските is described under the tantaliferous minerals.

Carnotite is described under the vanadiferous minerals. Test for uranium as in uraninite.

New Aneroid Barometer

The accompanying illustration shows a new aneroid barometer, invented and patented by J. C. Asten, of Upper Norwood, S. E., England. The instrument, which is made in large watch size, has a 2½-in. dial, and is capable of noting differences of elevation of 10 ft. up to 10,-

ASTEN'S NEW ANEROID

000 ft. The usefulness of such an instrument to engineers and others is plainly apparent.

A Large Dredging Company

SPECIAL CORRESPONDENCE

Some additional facts have now been learned relating to the new corporation known as the Natoma Consolidated, of California, which was referred to recently in the JOURNAL. The object of the consolidation is to control all the gold-dredging operations on the American river near Folsom and Natoma, as well as the operation of the Feather River Development Company, of Oroville. By so doing the operating costs will be decreased and the combined net earnings increased. Moreover the life of the combined dredging operations will be extended from six to 10 years, to a period ranging from 17 to 20 years. The total area of prospected dredging land involved in the corporation's holdings is about 6000 acres. It is estimated that in this area there are 287,700,000 cu.yd. of gravel, etc., containing, gross about \$29,724,000. In addition there are 3,000 acres of unprospected or partly pros-

pected dredging lands, the value of which has not been computed and is not included in the above statement.

The company takes in the ground, dredges, etc., of the Natoma Gold Dredging Company, the Folsom Development Company near Folsom and the Feather River Development Company's property and dredges at Oroville. The Ashburton Mining Company, of Folsom, is also expected to come into the combination. The Consolidated company will commence operations with 14 dredges and will, without delay, construct three more, one on the property of the Folsom Development Company, one on lands adjacent to the Natoma Development Company's ground, and one on the Feather River Development Company's land at Oroville. Later four additional dredges will be built on the ground of the Folsom Development Company.

The capital stock of the new company is \$25,000,000. In addition to the dredging properties mentioned, the new corporation will own the Natoma Land and Mining Company's land, water and vineyard departments; the Sacramento & Folsom Railway Company; the Sacramento River Company; the Folsom Rock Company and the Folsom Pipe Company. The present water supply of the Natoma Land and Mining Company will be largely increased by building storage reservoirs, so as to supply water to the dredges at all times. The American reclamation district, north of the Sacramento river and across the American river, will be laid out, developed and supplied with water. The combined flow of water will be some 8000 or 9000 miner's inches. Water will be sold to Sacramento and adjacent towns.

Eugene J. De Sabla will be president; Louis Sloss and Frank W. Griffin vice-presidents. Among other directors will be R. G. Hanford, W. P. Hammon, W. H. Crocker, J. C. Coleman, J. D. Grant and J. H. Follis. A. E. Boynton, secretary of the present Hammon companies, will be secretary of the new one. Offices are being prepared in the new Alaska Commercial building in San Francisco. It is expected that, among others, Francis Carolan, John Hays Hammond, Frank Drum and George Pope will become interested. It is expected also that the general management will rest in W. P. Hammon while the present general superintendent of one of the largest dredging companies in the State, will take a similar position with this company. All the persons mentioned are men of large means in this community and many of them have been for years connected with the mining industry of California.

Upon unwatering an old copper mine the water should be tested, and if found to contain much copper, should be precipitated by the well known method of passing it over scrap iron and old tin cans.

Rhodesia in 1908

BY W. FISHER WILKINSON*

The gold production for the year 1908 may be expected to reach £2,525,000 in value, which is £346,114 in excess of the production of 1907 (£2,178,886), an increase of 15 per cent. The accompanying table, compiled by the Rhodesia Chamber of Mines, gives the total gold production

WORKING COSTS

In the presidential address delivered to the Chamber of Mines on May 20, the following average costs of 11 of the principal mines, omitting the Wanderer mine, which is a low-grade property, working under exceptional circumstances, are given: The 11 mines crushed 534,332 tons and treated 271,443 tons of sands and concentrates. The costs per ton milled were as follows:

GOLD PRODUCTION OF RHODESIA TO MARCH 31, 1908.

	Tons Milled.	Gold, Oz.	Value.	Value per Ton.
Prior to Sept. 1, 1898.	*	6,471	£23,456	
Sept. 1, 1898, to June 30, 1899.	81,841	48,847	177,072	43.268.
July 1, 1899, to June 30, 1900.	104,746	57,621	208,877	39.88
July 1, 1900, to March 31, 1901.	140,716	89,258	320,457	43.54
Year ending March 31, 1902.	249,667	180,910	640,661	51.32
Year ending March 31, 1903.	338,156	201,107	709,461	41.96
Year ending March 31, 1904.	516,747	234,693	845,359	32.71
Year ending March 31, 1905.	787,936	309,516	1,113,068	28.25
Year ending March 31, 1906.	1,100,609	435,019	1,556,741	28.28
Year ending March 31, 1907.	1,417,723	560,750	2,012,543	28.39
Year ending March 31, 1908.	1,652,019	624,764	2,289,452	27.71
	6,390,166	2,748,956	9,897,147	30.97

* No details available.

from Southern Rhodesia to March 31, 1908. In the table the ounces are partly bullion ounces. It has been arranged for all declarations of gold from April, 1908, to be made in fine ounces; and the value of the ounce will be calculated as in the Transvaal at £4,247.73.

The output is largely made up of the returns from small mines or tributors working within the average five stamps. The September sheet, for instance, has 104 different names contributing to the total, of which only 14 have 20-stamp batteries or upward. At the close of 1907 the small workers were contributing about 35 per cent. of the output.

The principal mines are given in the accompanying list, compiled from the Sep-

SEPTEMBER PRODUCTION SOUTHERN RHODESIAN GOLD MINES.

	Tons Milled.	Stamps.	Total Yield.

tember returns. The total production of southern Rhodesia for that month was valued at £204,261 from 159,934 tons.

* Mining engineer, London, England.

crebody has lately widened out considerably at the sixth and seventh levels, being more than 100 ft. wide and all in pay ore, a discovery which has greatly improved the future prospects. To meet the cost of the new shaft and to double the mill capacity (a policy which the new discovery of ore mentioned above has influenced) £50,000 is being raised by a debenture issue. The Giant is one of the dividend-paying mines, having paid £17,812 in 1905-6, £35,625 in 1906-7 and £41,562 in 1907-8 on a capital of £250,000.

Another dividend payer is the Globe & Phoenix, one of the oldest of the Rhodesian mines. The depth of the workings are now 2300 ft. For the six months ending June 30, 1908, the 40-stamp mill crushed 37,546 tons and obtained a gross profit of £28,475, excluding depreciation and London expenses, the yield and costs per ton being, respectively, 42s. 1d. and 26s. 11d. Battlefields is another dividend-paying mine. The Eldorado mine, working on a conglomerate or so-called blanket ore, commenced crushing in September, 1907, and up to Oct. 31, 1908, treated 43,802 tons for a yield of £111,408. The estimated profit was £53,000.

The Wanderer is a low-grade mine or quarry which dealt with 190,377 tons during the year ending April 30, 1908. The yield per ton was 8s. 8.83d., and the working costs, 6s. 5.7d.

OTHER MINERALS

In the eastern part of Rhodesia the copper mines of Umkondo and Edmundian are being developed. The Edmundian started smelting in October. The reduction plant consists of pneumatic stamps and Elmore vacuum oil concentrator, and the smelting plant of calciners and reverberatories. The matte produced is shipped. Power is obtained from a hydroelectrical power plant situated four miles from the mine.

In the Bembesi district several diamond pipes have been discovered. Some diamonds have been found. Further work is required to establish the value of this discovery. The dispute between the Chartered Company and the De Beers, which claim exclusive rights to all diamond mines in Rhodesia is to be fought in the British courts. The claims of the De Beers company are opposed by the Rhodesia Chamber of Mines.

GOLD PRODUCERS

One of the successful mines of Rhodesia is the Giant, which for the year ending June 30, 1908, milled 65,074 tons with a 15 stamp mill and one tube mill, obtaining a recovery of 36.8s. per ton milled. The working costs, including development, total 15.5s., or 18.5s. if depreciation and London expenditure is added. Owing to the caving in of the main shaft, the successful operations have recently been thrown back, and about six months will be required to sink a new shaft. The

The blanketing for use at the Giant mine, Rhodesia (*Journ. Met. Chem. and Min. Soc.*, Nov., 1908), is 3 ft. wide and torn into strips 4½ ft. long. The canvas is hand-washed in tubs. The blankets are washed every half hour. Revolving tables for washing the blanketing were tried, but the blankets could not be cleaned of the fine heavy concentrates that way.

The slope given the walls of the open cut at the Broken Hill Proprietary mines, Australia, varies from ½ to 1 to ¾ to 1.

The Microstructure of a Complex Ore from the Frisco Mine, Idaho

By WILLIAM CAMPBELL*

Two specimens of "magnetic lead ore" were sent to me by W. R. Ingalls, with the information that he had obtained them at the Frisco mill, Gem, Idaho, where it was being separated as the magnetic product by a Dings machine, equipped with a horizontal, endless belt (instead of the usual shaking tray) and thus enabled to work with wet material. He reported that this lead ore was strongly magnetic, the pull on a piece held near the mag-

iron, 12.3 sulphur, 12.7 zinc and 9.8 oz. silver.

In the hand specimen the two pieces of ore were fine-grained, showing tiny faces of galena in the midst of a good deal of dark, dull material. Scratching with a knife gave a brownish streak, but the specimens were hard. Some of the ore was powdered, in which state the magnet picked up particles having a metallic luster and a black streak, very hard, probably magnetite.

The two specimens were next ground flat on a lap and carefully polished on various grades of French emery paper and finished on a rouge board.[†] Under the microscope they were seen to be a very intimate mixture of galena, blende, magnetite, calcite and other gangue as the

however, has a dark metallic streak, and probably is magnetite. Fig. 2 is similar; shows a characteristic cross-hatched structure. It can be scratched with a needle, showing rough magnetite; calcite, black due to etching and vertical illumination, but with oblique light showing fine white grains or crystals; galena as the bright white groundmass as before. Fig. 3 shows the same rough magnetite and black calcite. The mass of bright galena is the largest patch in the specimen. The more common structure is seen in Fig. 4 a complex of galena and gangue in which some blende and magnetite occur. Fig. 5 shows an area with much rough magnetite in grains, set in a groundmass of galena in which small patches of gangue occur. In other parts of the specimen several grains

FIG. 2

FIG. 3

FIG. 4

FIG. 5

FIG. 6

FIG. 7

FIG. 8

nets being pronounced, and that the magnets lifted from the belt pieces weighing an ounce or more. The greater part of this magnetic lead ore was collected by the jigs along with blende as a lead-zinc middling, which was fed to the Dings machine, it making a magnetic lead product and a non-magnetic zinc product. According to Frederick Burbidge, general manager of the Frisco Mining Company, Limited, the lead concentrate thus obtained had approximately the following analysis: Lot of 35 tons—22.3 per cent. lead, 31.2 silica, 13.9 iron, 13.6 sulphur, 13.5 zinc, and 10.1 oz. silver. Lot of 75 tons—22.1 per cent. lead, 26 silica, 17.8

following description will show: The smaller specimen showed bright, easily scratched galena which was evidently the last mineral to be deposited. Fig. 1 (magnified 40 diameter), shows this as the white groundmass. The dark well polished material is calcite, which on etching with weak nitric acid shows a very fine structure, as if it had been crushed. Very thin veins of galena cut it in all directions. The rough metallic mineral in irregular grains standing out in relief is seen embedded in the calcite and is evidently earlier. It has all the appearances of magnetite and on etching with concentrated hydrochloric acid

of black greasy quartz in relief were seen.

The larger specimen contains many large and small rounded grains of quartz which is apparently one of the oldest if not the oldest mineral present. Fig. 6 shows some of these small grains as intensely black spots. The rough grain in the center of the field is magnetite while the dark mineral, covering most of the ground, is blende. The interstitial spaces are filled with bright white galena, evidently the last constituent to form.

In Fig. 7 the black mass is quartz; the white groundmass is galena in which are set irregular grains of blende. Fig. 8 shows several dark grains of quartz, some rough magnetite and the usual white galena. The dark gangue in the lower part

*Adjunct professor of metallography, Columbia University, New York.

[†]"The Microscopic Examination of Opaque Minerals," *Economic Geology*, Vol. I, p. 751.

of the figure is probably barytes. It has a white streak, is soft and, with concentrated hydrochloric acid shows a well marked cleavage. There is a good deal of this mineral present in the specimen, forming a complex with blende, and in one place it includes a few small patches of chalcopryrite of later origin. The fine needles of gangue, seen in Fig. 8 embedded in the galena, are probably the same material.

Thus the very complex appearance of the specimens to the eye is explained by the microstructure which indicates the following order of deposition: quartz, magnetite, barytes (or some other gangue mineral), calcite and blende and, last of all, galena.

Federal Aid for State Mining Schools

SPECIAL CORRESPONDENCE

Representative Foster by instruction of the Committee on Mines and Mining on Jan. 16, reported to the House Senate bill 3764 passed by the Senate on May 15 last. This bill in different forms was simultaneously introduced in the two houses last spring and then provided for the appropriation of a portion of the proceeds of sales of public lands for the endowment of schools or departments of mines and mining in the various States. The House bill as now reported strikes out all after the enacting clause of the Senate measure and inserts a new draft nearly identical with the Foster bill of the last session (H. R. 20591). The measure provides that there shall be appropriated from the sale of public lands \$5000 during the fiscal year beginning July 1, 1909, \$10,000 for the fiscal year beginning July 1, 1910, \$15,000 for the next fiscal year and so on up to \$25,000 which is then made a permanent annual appropriation for each State and Territory for the establishment and maintenance under the control of the Secretary of the Interior of a school or department of instruction in mines and mining. Section 2 provides that if there be already established in any State or Territory a State school of mines and mining, or if there be a department of instruction in mining connected with any institution of learning controlled by a State the funds shall go to the already existing school or department. If there are two schools or departments of mines and mining the money appropriated is to be equally divided between them. In States where there is no such department of instruction and no agricultural college, some other State institution will be selected as the recipient, or in the event that there is no institution whatever controlled by the State, the Secretary of the Interior is to designate some accessible and convenient place where the school of mines and mining shall be located. The money ap-

propriated is to be used only for "instruction, research and experiment (including the employment of instructors and experts, the purchasing of apparatus, supplies, and books, and the equipping of laboratories) in mining, mining machinery (with the application of electricity thereto) mining engineering, ore treatment, metallurgy, assaying, and chemistry and geology, so far as these sciences relate to minerals and mining, with a view to teaching a practical and scientific knowledge of the best and safest methods of mining and carrying on the business of mining and of producing gold, silver, coal, and other minerals, oil, gas, and medicinal waters, and also the concentrating, smelting, refining, and other preparation of the same for marketing, so far as the same may be necessary and appropriate to the mineral resources of the State or Territory in which said school or department of instruction in mines and mining shall be located, and especially for the study and prevention of explosions, fires and other dangers incident to the carrying on of mining and the mining industry, in order to secure the most intelligent conservation, use, and development of the mining and mineral resources of the country, to make the life of miners more safe, property in mines more secure, and to promote the general welfare of miners and operators of mines."

The head of each school or department of mining is to report annually to the governor of the State or Territory in which his school is located and a copy of the report is to be sent to the Secretary of the Interior. The money is to be disbursed upon warrant of the Secretary of the Interior to the State or Territorial treasurer who is to pay it over upon order of the board of trustees or other board of control of the institution.

In support of this bill the committee report calls attention to the growth of mine disasters and says: "We believe that the modest expenditure of the Government in the establishment of these schools of mines and mining where the correct principles of mining will be taught is of importance. We believe that the means of education which these schools will afford will, in time, reduce the loss of life and property to the minimum," besides affording other benefits.

In a letter to the President signed by Charles D. Walcott, which is also submitted, Mr. Walcott says: "There can be no question that the mining industry would be greatly benefited and extended by the more thorough training of men who are engaged in mineral production. At the present time a considerable number of mining engineers are graduates from out larger educational institutions, but the great mass of the mineral producers have not been thoroughly trained."

This bill contemplates only the appropriation of the proceeds of the sale of public lands outside of the "irrigation

States." The following statement gives the amount available for the purposes of this bill from the sale of such public lands for the year ending June 30, 1908: Alabama, \$23,334; Alaska, \$18,373; Arkansas, \$300,014; Florida, \$64,250; Iowa, \$117; Louisiana, \$79,464; Michigan, \$43,731; Minnesota, \$24,415; Mississippi, \$17,042; Missouri, \$12,197; Wisconsin, \$19,027; total, \$1,103,165 for the year.

Drawback Regulations on Metals

SPECIAL CORRESPONDENCE

Treasury regulations of April 16, 1901, providing for the allowance of drawback on babbitt metal manufactured by Merchant & Company, of Philadelphia, in part with the use of imported lead and antimony, have been extended so far as applicable to cover the exportation of babbitt metal manufactured by the Frictionless Metal Company, at its factories at Chattanooga, Tenn., and Richmond, Va., with the use of imported lead and antimony. The drawback entry must show the total quantity of babbitt metal exported and the quantities and percentages of imported lead and antimony used in the manufacture. In liquidation the quantities of imported lead and antimony which may be taken as the basis for the allowance of drawback may equal those declared in the drawback entry provided they shall not exceed 83 lb. lead and 14 lb. of antimony for each 100 lb. of exported babbitt metal.

Treasury regulations of April 26, 1908, providing for the allowance of drawback on the exportation of iron tubes, pipes, flues and stays manufactured by the National Tube Company, wholly or in part from imported Swedish charcoal pig iron, have been extended so far as applicable to cover similar articles manufactured by the Reading Iron Company, of Reading, Penn., wholly or in part from the same imported material. The allowance shall not exceed 144 lb. of imported charcoal pig iron for each 100 lb. of exported product where the latter is manufactured wholly from imported material and a proper proportion of this amount when the exported tubes, pipes, etc., are manufactured partly from imported material.

A few years ago deep-level mining companies on the Rand, South Africa, were looked upon as questionable ventures, but now three deep-deep-level mines—the Robinson Deep, Sinner & Jack East and the Village Deep—are producing and the mining costs, which exclusive of development are, respectively, 12s. 10d., 16s. 8d. and 15s. 2d., are now lower at these mines than was the cost at most of the mines operating on the Rand at that time.

Water-tight Bulkhead Door

In many mines the water is confined either to the vein or to fractured zones in the country rock, while the rest of the ground is comparatively dry. Such conditions prevail at Eureka, Nevada, in the Richmond-Eureka mine, and also in the Pachuca and Real del Monte district in Mexico. Many mines have been drowned out through crosscutting unknown portions of the ground on old levels, or through driving new levels, without providing a water-tight bulkhead in the first solid ground near the mouth of the crosscut. Such a bulkhead keeps the sudden flow of water from drowning out the pumps, and at mines previously dry, if the ground between the shaft and the water-bearing zone is solid, this bulkhead will hold back the water until pumps can be installed. Indeed it seems as though ordinary prudence would dictate the building of a water-tight bulkhead near the mouth of such exploratory crosscuts.

In the later days of the bonanza period at Eureka, owing to failure to take this precaution, the Richmond-Eureka mine was lost when a heavy flow of water was unexpectedly struck in the fractured limestone on the bottom level of the Locan shaft. Since then the mine has been unwatered and a bulkhead closed by a door, constructed as is shown in an accompanying illustration, has been built. In the future at this mine when exploring the water-bearing zone a bulkhead will always be built for protection.

The bulkhead door that inspired the design illustrated in this article was used in the Real del Monte and Pachuca mines in Mexico; the redesigning to strengthen the door was done by C. F. Moore, chief engineer of the United States Smelting, Refining and Mining Company. This door is for use with concrete bulkheads.

In building the bulkhead, first a cross drift extending a few feet into the rock on each side of the crosscut or drift is driven at anchorage for the bulkhead. Bolts for fastening the door casing are placed in the concrete, and when the whole has become solid the casing is bolted in place on the side that faces the expected source of water. The door and casing are made of cast iron. While driving the drift the door is left open, especially at blasting time on account of concussion. If water is met with, the door can be closed even if there is a considerable flow of water coming out of the drift.

In using this door at the mines of different companies affiliated with the United States Smelting, Refining and Mining Company, it has been found that frequently there is leakage at the edges of the door. So to avoid that possibility a gasket, made out of old rubber belting, is hung from the casing. After closing the door, suitable lengths of railroad iron are put across the bulkhead, and bolts, with

their T-ends hooked into recesses provided in the door and with their heads shouldering against the rail cross pieces, are used to bring the door home against the seat. This door is air-tight as well as water-tight, so that it can be used in isolating a level in case of fire. By means of the water gate, the flow of water can be regulated to the capacity of the pumps. The door has given great satisfaction wherever used, and has been found amply strong to withstand great pressures.

Peroxide Method for Determining Lead

W. S. Medell (*West. Chem. and Met.*, IV, pp. 152-156) has published some advance notes on a new method for the determination of lead. The proposed method is called the "peroxide method for the estimation of lead" and is said to be short, accurate and not affected by contaminating elements. The permanganate and iodometric titrations are about the most satisfactory volumetric methods in use. The new method consists of precipitating the lead from a caustic-soda solution as peroxide by bromine, reducing the peroxide with an excess of reducing agent and then titrating the excess with a permanganate solution.

At the beginning of the investigation oxalic acid was used as the reducing agent in a sulphuric-acid solution, but proved unsatisfactory. Phosphoric acid was substituted for the sulphuric acid with better results except for the time element. The substitution of ferrous ammonium sulphate for the oxalic acid and the use of the phosphoric acid solution achieved the desired result.

The following reagents and standard solutions are used: Ortho-phosphoric acid; a 10-per-cent. solution of caustic soda; a 5-per cent. solution of potassium bromide saturated with bromine; a standard solution of ferrous ammonium sulphate; and a standard solution of potassium permanganate. The ferrous ammonium-sulphate solution contains 18.958 grams of the pure salt per liter of water; 1 c.c. will reduce 0.005 gram of lead from PbO_2 to PbO . The permanganate solution contains 1.528 grams of the pure salt in a liter of water. The permanganate and the ferrous ammonium-sulphate solutions are standardized against each other.

METHOD OF ANALYSIS

Dissolve 0.5 gram of the ore in a 3¼ in. casserole with 10 c.c. of sulphuric acid (1:1) and 5 c.c. of nitric and hydrochloric acid; the proportion of these in the 5 c.c. varies with the ore. The solution is evaporated to white fumes and if manganese is present a crystal or two of sodium sulphite is added to reduce manganates that might be present. When cool, the solution is diluted with water to about 50 c.c.,

allowed to stand, then boiled, cooled and filtered by decantation, retaining as much as possible of the sulphate in the casserole. The residue is washed with sulphuric acid several times by decantation. A hot solution of caustic soda (10 c.c. of the 10-per cent. caustic solution to 20 c.c. of water) is poured, 15 c.c. at a time, through the filter and caught in the casserole containing the residue. The filter is then washed with about 100 c.c. of hot water and the washings and residue transferred to No. 3 beaker. The contents of the beaker are boiled until the lead sulphate is dissolved, then cooled to about 95 deg. C.; from 15 to 35 c.c. of the bromine water are added and the solution is stirred vigorously for a few seconds. The peroxide is at first yellow colored but soon darkens to the usual liver color. It is necessary to be sure of an excess of bromine and to heat the solution just below boiling for at least five minutes after its addition, but not long enough to drive off the excess of bromine. The solution is stirred while heating, and after removal from the hot plate is allowed to settle. The solution is filtered through a 11-cm. filter, retaining the bulk of the precipitate in the beaker, and filling up the filter with cold water as soon as the solution has passed through. The precipitate is washed by decantation with three successive portions of 25 c.c. of water each. The filter paper is then transferred to the beaker and 250 c.c. of cold water and 5 c.c. of phosphoric acid added. A measured amount of the standard ferrous ammonium-sulphate solution is added in excess to dissolve the peroxide, using a rubber policeman to break up the lumps of peroxide. The solution is then titrated with the permanganate solution.

The reactions of the process are:

The results obtained by this new method check well on the same sample, and check closely results obtained gravimetrically and by the molybdate method. Bismuth apparently does not interfere.

The total value of the metals and minerals raised in Tasmania during the quarter ending Sept. 30, 1908, according to the report of the Secretary for Mines, was £421,019, as compared with £365,703 for the period ending June 30, 1908. Blister copper, tin ore, silver-lead ore, gold and coal in the order named were the chief products.

Oroville Dredging, Limited

It has been decided to convert this from an American company into a British, exchanging each \$5 share for one of £1. The market is in London rather than in America and F. W. Baker is perfectly frank in saying that the policy of a British management toward its stockholders is preferable to an American. At a recent informal meeting at London, W. P. Hammon made the following statements:

"The business as a whole is in good condition. The dredgers are working regularly with the exception of shortage of power occasioned by the very dry period in our country. The electric power of our company is generated by the streams from the mountains, and in an extraordinarily dry season like the last there is a shortage of water, and there was quite a loss of running time—perhaps 20 per cent. during September and October. That, however, does not occur frequently. Although we had considerable trouble during 1908, the demands for power in our country seem to be in advance of the supply. We are gradually overcoming that, and now there is sufficient power available to give us continuous running time. The results of the business in 1908 are not quite equal to those of the preceding year, for various reasons, to one of which I have referred. The life of the business based upon the amount of property worked to date at Oroville would give us a life of 10 years. On the Bear River we have been confronted with more or less difficulties, but we are working out of them gradually, and we have before us now a body of ground that promises good results, and our machinery is equal to it. We will, however, be obliged to eliminate a certain portion of ground that contains bodies of very heavy clay which it is impossible to wash or disintegrate by any appliances that we have been able to invent up to this time. The taking up other properties is, I think, a good business venture. We are well organized; we are as well equipped for that line of business, perhaps, as any operators in the field, and we have had as much experience in our business as any other company in existence. We have educated our men in the field, and they are practical. If we take over a property in any other country we shall equip it from those men who have received their training in the practical operations of the business. Working the Bear River with the one 7-ft. machine now at work, the life of the property would probably be 20 years. The life of the two properties, the Oroville and the Bear River, is about 14 years."

According to F. W. Baker, chairman of the company, owing to the financial situation which arose a year ago, certain holders in Boston sold out. The London market has absorbed since the company was organized about 220,000 shares, and today he knew of no big shareholders who were

desirous of selling. On the contrary he was assured that they would not sell, at any rate, at anything like present prices. If the shares went to 20 or 25s, they might be tempted to sell, but at 8s. they looked upon the price as idiotic. Mr. Hammon holds about 50,000 shares, and he is not a seller.

The company is now examining a dredging property in Colombia, which is represented as comprising 25,000 acres, of which 300 acres are expected to give a profit of £600,000. The vendor of the property is to get one-fourth of the stock of any company to be organized and £7000 in cash.

Steel Corporation

The preliminary statement of the United States Steel Corporation for the quarter ending Dec. 31 shows results as follows:

Net earnings over expenses	\$26,225,483
Sinking fund, depreciation, etc.	\$ 5,213,822
Interest and sinking fund	7,311,963
Total charges	\$12,525,785
Balance	\$13,699,700
Dividends on stock	8,846,432
Balance	\$ 4,853,268
Add adjustments	289,183
Surplus for the quarter	\$ 5,142,451

The dividends declared were 1¼ per cent. on preferred—\$6,304,919—and 0½ on common—\$2,541,513.

These figures give the following statement for the year:

	1907.	1908.
Net earnings	\$160,364,477	\$91,826,620
All charges	\$ 56,309,109	\$45,942,857
Dividends	35,385,728	35,385,728
Appropriations for new w'k.	54,000,000	
Total	\$145,784,837	\$81,228,585
Surplus	\$ 15,179,640	\$10,497,935

The unfilled orders on hand Dec. 31 reached a total of 3,603,527 tons; an increase of 181,550 tons over Sept. 30, but a decrease of 1,039,026 tons from Dec. 31 of the previous year.

Mining Legislation at Washington

SPECIAL CORRESPONDENCE

Representative Martin, of South Dakota, has introduced a bill (H. R. 26477) for the establishment of mining experiment stations intended "to aid in the development of the mineral resources of the United States." The bill provides for the establishment of such stations "in each of the States and Territories which are known to contain natural deposits of the precious metals in paying quantities when in the judgment of the Secretary of Commerce and Labor it will subserve and promote the development of the mineral resources of the United States." At each station there is to be a geologist receiving

\$3000 per annum and a chemist at \$2000, the outlay for establishing, equipping and maintaining each station to be \$5000. The duties of these officers are described in Section 3 which reads:

"Sec. 3. That it shall be the duty of such geologist and chemist appointed under this act to receive for assay or analysis all rock, cement, clay, or other mineral-bearing substance that may be deposited with them by any citizen of the United States and make a proper classification or assay of each sample of rock, cement, clay, or other mineral-bearing substance, for the purpose of ascertaining the exact amount of gold, cinnabar, silver, copper, wolfram, tin, or any other mineral known for its value in the arts and sciences or used in commercial transactions, and to furnish, at a nominal charge to be regulated by the Secretary of Commerce and Labor to each depositor of rock, cement, clay, or other mineral-bearing substance, a full assay or analysis, showing the quantity and quality of each and every mineral found in said rock, cement, clay, or other mineral-bearing substance so examined by them.

"That the person depositing such sample as aforesaid shall, at the time of making such deposit, make oath before any person authorized by law to administer oaths stating the place from which such sample was taken and by whom taken, and in addition said chemist and geologist shall be each of them authorized and empowered to administer such oath; and the making of any false oath as to the facts set forth in said affidavit shall constitute perjury and be punished as a crime of perjury is punished under the laws of the State regulating the punishment of perjury."

Full records are to be kept and regular reports made to the Secretary of Commerce and Labor and whenever the geologist in charge of a station is not otherwise "necessarily" occupied he shall "personally explore and carefully examine the mineral regions within his jurisdiction, and especially at points of new and recent discovery and make full and careful report of such explorations and examinations at such times and in such manner as may be required and directed by the Secretary of Commerce and Labor, and he shall be allowed his actual and necessary expenses while so engaged."

Many superintendents do not use sufficient discretion in the selection of men to draw timbers when robbing work is being carried on. Only skilled men selected for their coolness, resource and courage should be employed to perform this work. These men should be paid good wages, and under no circumstances should they be put on piece work, for when this latter plan is followed, the men always take risks which otherwise would not be attempted.

Spelter Production of the World

The following estimate of the world's Harry R. Merton & Co., of London. The production of spelter is made by Messrs. figures are in long tons:

	1907.	1908.
Belgium.....	152,060	162,420
Rhine district.....	69,160	72,050
Holland.....	14,755	16,985
France and Spain.....	54,720	53,615
Great Britain.....	54,855	53,940
Silesia.....	136,260	141,410
Austria and Italy.....	11,180	14,000
Poland.....	9,585	9,600
Total Europe.....	502,575	525,020
Australia.....	980	1,070
United States.....	223,265	185,700
Total.....	726,820	711,790

The European producers show an increase of 4.6 per cent.; but there was a decrease of 16.8 per cent. in the United States. The result is a decrease of 15,030 tons, or 2.1 per cent., in the total production. These figures are preliminary, and subject to correction by complete returns; but they are a close approximation to the actual totals.

Leases of Phosphate Lands

SPECIAL CORRESPONDENCE

Senator Smoot, of Utah, has opened a campaign to compel the Secretary of the Interior to restore to entry after examination and classification by the Geological Survey the phosphate-bearing lands of the United States. His first step has been the introduction of a bill to this end (S. 8609), in which it is provided that the President shall appoint a commission of three members each to be paid \$10 per day and expenses (unless already a Government employee), whose duty it shall be to clear the title of the lands, classified by the Geological Survey as phosphate lands, of all entries, claims, and locations invalid because of nondiscovery of mineral, failure to perform the annual labor and improvement required by law, or because of failure of entrymen, claimants, and locators, to perform any of the material acts required by law as a prerequisite to entry, claim, and location. The proposed commission is to have the power to administer oaths, to compel the attendance of witnesses, to visit the claims involved, and take judicial notice of all things observed, and to do what may be necessary to determine the facts in the most direct manner. The findings of this commission as to the validity of entries, locations, and other claims on lands not yet patented by the United States are, on approval of the Secretary of the Interior, to be conclusive.

The important feature of the bill is found in a proposed system whereby the Secretary of the Interior is empowered to issue leases or licenses to work the phosphate deposits belonging to the United

States on such terms as he may deem best, or as may be directed by Congress; provided, that the leases and licenses shall be on such terms as to insure the proper development of the deposits and the utilization of the output in the United States. There is to be inserted in all future grants and patents a reservation of all deposits of phosphates, together with the right on the part of the Government, as well as of its licensees or lessees, to enter upon the lands and conduct mining operations under such rules and regulations, formulated by the Secretary of the Interior, as will insure the surface owners from loss or damage.

A Court of Patent Appeals

SPECIAL CORRESPONDENCE

In support of a plan to establish a United States Court of Patent Appeals, hearings were granted by the House Judiciary Committee Jan. 5 to a committee appointed by the American Bar Association on patents, trade-marks and patent law. This committee consists of Joseph R. Edson, R. S. Taylor, Arthur Stewart, Fred P. Fish and O. R. Barnett. The bill which it is desired to have Congress pass provides for a court with five justices, the chief justice to be appointed by the President and the associates by the chief justice of the Supreme Court of the United States, two sitting for three years and two for six years, terms of court to be held annually in Washington. The court would have jurisdiction to hear and determine appeals and writs of error from final judgments and decrees in the circuit courts of the United States in cases relating to patents for inventions; from final judgments and decrees in cases relating to patents for inventions rendered by any other court having jurisdiction under the laws of the United States to hear and decide such cases in the first instance; provided it shall have no jurisdiction in cases originating in the court of claims. After the proposed act shall take effect "no appeal or writ of error shall be taken from any circuit court or other court of the United States to any circuit court of appeals or other appellate court in any case to which an appeal or writ of error may be taken to the United States Court of Patent Appeals under the provisions of the act."

In support of the proposal it is agreed that owing to the present requirement that patent causes be heard in the first instance by United States circuit courts, and then on error or appeal finally (save in case of writs of *certiorari*) by the circuit courts of appeals, there are now practically nine supreme courts for patent cases in the country. The effect of this is the issue of many conflicting opinions as to patents, which prevents them from having the

same force and effect throughout the United States and thus partially destroys their value. It is argued that a court created in the way now proposed would be superior in the decision of patent cases to any ever heretofore created. The bill has been indorsed by the chief patent bar associations of the United States and by the American Bar Association.

Washoe Smelter Case

Judge Hunt in the Federal Court on Jan. 25 handed down a decision in the so-called smoke case, wherein the farmers of Deer Lodge valley sought to have the smelter of the Anaconda Copper Mining Company at Anaconda, Mont., closed because the gases therefrom were ruinous to vegetation and live stock. In essence Judge Hunt denies the application for an injunction closing the smelter, and no damages are awarded to the complainants, with the exception of Fred G. Bliss, who is granted \$450 a year for damages since 1904.

The Court found that there had been some damage from arsenic in the vicinity of the Washoe smelter, but no appreciable damage from sulphur.

The decision says: "Finally, in the last analysis when, in connection with the attitude of Mr. Bliss, direct and vicarious, we weigh the uncertainty of his proof as to the amount of past damage done to his land, or of future damage to be done to his pasture by the acts of these defendants, together with the fact that he has not resorted to a court of law to recover any damages at all, and balance these facts against the great injury that would be done to many interests, I hold that, under the evidence as he has submitted his case, discretion, wisely, imperatively guided by the spirit of justice, does not demand that the injunction as prayed for should issue."

The Court orders a further hearing in the matter on Feb. 15 to ascertain if there is not a possible means of so treating the flue dust as to reduce the quantities of arsenic now suffered to be released from the stack, and states that it may thereafter make any specific order such as may be equitable and right and that it will retain the bill in diligent effort to afford all the relief reasonably possible under its allegations.

A free-milling gold ore at the Giant mine, Rhodesia (*Journ., Chem., Met. and Min. Soc. of South Africa*, Nov., 1908) is crushed coarse in stamps, fine-ground in tube mills, and then concentrated on blanket and canvas tables. By passing the battery pulp over amalgamation tables and treating the concentrates from the tables on amalgamation tables an extraction of 87.7 per cent. of the gold is obtained, 55 per cent. of the total gold being caught on the blanket tables.

Colliery Notes

One large coal company has adopted the plan of having sign boards in all parts of its underground workings; these notices point the way leading to the nearest exit.

The Reading Coal and Iron Company has completed plans for stripping a large coal deposit in the Heckscherville valley, north of Pottsville. It is estimated that this stripping will produce 10,000,000 tons of coal.

Discipline in the mines of Northumberland is enforced by fines and prosecutions. Discretion as to the amount of the fine is left to the judgment of the mine manager, so that the offending miner is not always taken before a magistrate and the offense made public.

Notice plates for coal or metal mines may be painted on glass and the whole covered with an elastic cement. The inscription is thus protected from air and moisture; the cement also aids in holding the fragments of glass together if the plate should be damaged.

Experiments have recently been carried on in England for the purpose of providing some method whereby the presence of small quantities of gas may be detected. The latest of these experiments has been worked with a double convex lens of blue glass, magnifying three to five times; it is stated that a very fine cap of gas can be seen through a lens of this description.

At a recent meeting of the North Staffordshire Institute of Mining and Mechanical Engineers the fact was brought out that in explosions due to gas alone the territory visited by the destructive agency is limited in area. The consensus of opinion was that it was only in explosions where coal dust had taken a part that the explosive force had passed through the entire mine.

In one district in Canada, the mine managers have found it advisable from the standpoint of economy, to have their ventilating fans so constructed that they can run them one way in summer and the reverse in winter. Reversible fans in all coal mines would not be a bad idea, for in the case of mine explosions, mine fires and other similar accidents, it is often best to reverse the system of ventilation.

To have two separate methods of shaft signaling from an underground landing to the engine house on the surface is a safety precaution that is most advisable, although many superintendents consider such practice as an exaggerated safety refinement. The electric signal with the single stroke bell, is, of course, the system to be generally used; in case of derangement in the electric system, the ordinary wire rope with rapper signal should be available.

The most modern screening plants recently constructed at different European collieries are entirely driven by electric power from a main generating station, each different unit being provided with separate motors, so that the break-down of any one part will not seriously affect the working of the plant as a whole. One special feature about these plants is that ample room has been allowed all around the various parts, with the result that all machinery is easily repaired; the plans also show that there are none of those cramped and dangerous passages usually met with on screening plants of considerable size.

James Ashworth gives it as his opinion, that 1 per cent. of firedamp in a mine is alone sufficient to carry a strong initiatory flame for a long distance. The same authority claims that with our present ordinary method of testing for gas, a fire-boss will not observe less than 3 to 3½ per cent.; he states that this condition is largely due to the fact that if the lamp's flame is lowered so far as to make a keen test, there is a great risk of its becoming extinguished. Mr. Ashworth further emphasizes the importance of practically testing every fire-boss at periodical intervals, as to his capability to see a firedamp cap of at least 2 per cent.

As a result of recent experiments conducted to determine stresses on winding ropes, it was found that the greatest stress on a winding rope does not occur at the beginning of a wind, as is the prevalent idea. In every case the application of the stresses to the winding rope (both ascending and descending) was shown to be very gradual. The greatest stresses on the winding rope were due to the vibrations of the cage. These vibrations in the first instance were caused by (1) the pulsations of the engine, in the case of an inferior type of machine; and (2) the sudden checking of speed by shutting off the steam, or by the application of the brakes.

Although subjected to influences which the average person would consider as injurious to health, the coal miner as an individual, is comparatively immune from disease. In discussing this question, members of the medical profession have advanced many theories as responsible for this condition. One doctor states that the miner works in a place absolutely free from germs, and that the poisons of the atmosphere never get to the miner while he is at work. It is also asserted that there is some atmospheric action of the sulphur or the coal dust with which the miner comes in daily contact. Sulphur is recognized as an active germicide. This same authority states that the wound a miner receives, no matter how severe, rarely suppurates or becomes inflamed.

The question has often been asked as to what connection there is between the explosibility of any particular coal dust

and its percentage content of volatile matter. Recent experiments by a European commission seemed to show that the dust of certain coals having as low as 20 per cent. volatile matter, explodes even more readily than some dusts where the volatile matter averages from 30 to 40 per cent. It is probable we shall some day discover that the percentage of volatile hydrocarbon in a coal has no more connection with the degree of explosibility of the dust than it has with the coking qualities of a coal. The coking or non-coking qualities of a coal are now known to be largely due to its physical structure; this same condition may be the principal factor that causes one dust to explode more readily than another.

With reference to the provision of greater safety in our coal mines, many suggestions are made that are most unnecessary, if not impracticable. From an important source it was recently advised that legislation be enacted to require separate traveling-roads for the men working in coal mines. It seems that the number of accidents occurring on haulage-roads have been greatly exaggerated. Investigation shows that it is not as dangerous on an ordinary haulage-road in a coal mine as it is on the streets of our large cities. The alternative suggestion that haulage-roads be widened so as to leave room to walk on each side is also impracticable in many cases because of bad roofs. There are many important improvements that mine owners should be compelled to adopt, so there is no reason for loading them with any unnecessary burdens.

The Lehigh Valley Coal Company, as an experiment, has installed an oil-burning locomotive in one of its mines at Hazleton, Penn., and another at Seneca. The increasing length of hauls has caused the expense of underground transportation to grow rapidly in the last few years, and it is hoped that the oil-burner will bring about an economy in this branch of the industry. Of course, these motors can only be used in mines free from gas. The advantage of oil as a fuel, for use in the mine, is that its combustion creates no fumes to choke the gangways and interfere with the breathing of the miners. It is also true that smoke from these oil-burners is a negligible quantity. The new motor at Hazleton weighs 15,500 lb., is 15 ft. long and 5 ft. high. It has four driving wheels 24 in. in diameter, and runs on a track of 42-in. gage. It has been built to take up as little space as possible. The top of the smoke stack is even with the top of the boiler, and the cylinders lie close to the sides. The oil-burner at Seneca is practically the same, except that it runs on a 3-ft. track. Either of the two machines is capable of hauling from 12 to 15 loaded mine cars up a 3-per cent. grade, and is expected to do the work of ten mules.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres. and Treas. ROBERT McKEN, Sec'y.
505 Pearl St., New York.
London Office: 6 Boulevard Street, London, E. C., Eng.
CABLE ADDRESS "ENGINEJOUR, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs. Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.
Our circulation for December, 1908, was 42,500 copies.

The Situation in Copper

The exaggerated reports about the accumulation of an immense stock of unsold copper, accompanied by the decline in the price for the metal, have put the ideas of the ill-informed at sixes and sevens. Some persons have the notion that the price for copper is on the road to 10c. per lb., whereas others are confident "that copper will sell above 16c. before it sells below 14c." The latter are evidently ignorant that the price is already below 14c. These wide differences of opinion are due to failure to take advantage of the accurate information that is available. Misinformation is greedily accepted when it bears out preconceived ideas or cherished wishes.

For example, one financial paper stated on Jan. 21, that electrolytic copper had been sold that day at 14 $\frac{3}{4}$ c., while another stated on the following day that it was being held at 14 $\frac{1}{2}$ c. As a matter of fact, electrolytic copper had been offered freely for a week previous at 13 $\frac{3}{4}$ c. by first hands, who would have been glad to dispose of some millions of pounds at that figure if the business had been forthcoming. By Jan. 18, the price in London had fallen to such a point that cathodes could be taken out of store, and delivered in New York at 13 $\frac{1}{2}$ c. Does anyone suppose that holders of large stocks in this country would not have been glad to let metal go at that figure, and replace it (if desired) by importation from England?

There is no great mystery as to the present situation in copper, which may be summarized as follows: Production in America is going on at the largest rate on record. Consumption is still below the normal. On Jan. 1 there was a considerable stock of unsold refined copper, but nowhere near so large as represented. However, the idea that there was no stock in this country was rather cultivated during the last quarter of 1908, and when speculators who had entered into large commitments in the London market awoke to the fact that the statistical situation was different from what they supposed, liquidation of their accounts ensued, causing the recent decline in prices. In the meanwhile, domestic manufacturers, pretty well conversant with the actual situation, have continued to refrain from buying, and production going on at undiminished rate, stocks have further accumulated

since Jan. 1. The market is at present in a precarious condition, and will become more so as long as manufacturers hold aloof. It is the ultimate consumer who possesses the key to the situation. The world's stock of copper is not yet so big as to be a great drag on the market for a long time after consumption regains its normal rate. The question is simply how long we have got to wait for manufacturers to begin to buy.

The Lick Branch Colliery Explosions

The Lick Branch mine of the Pocahontas Consolidated Colliery Company was recently the scene of two disastrous explosions. The first, Dec. 29, resulted in a loss of 51 lives; the second, by which 65 men were killed, occurred at 8:30 a.m., Jan. 12.

After the first explosion a coroner's jury exonerated the company from all blame. On Jan. 18, another coroner's jury, investigating the second explosion, returned a verdict stating that it had been caused by an overcharged shot, which exploded in room 21; it was further stated that no blame should be attached to the Pocahontas Consolidated Company or to the Lick Branch colliery officials.

The investigations of these explosions were along customary lines, so there is small room for discussion. Some excitement has been caused by published statements over the signature of the president of the United Mine Workers of West Virginia, in which it is charged that the two explosions in the Lick Branch mine were due to flagrant violations of the mining laws; this official demands that the legislature order an immediate investigation. Among other charges brought against the company is a statement that many galleries in the mine have been driven from 175 to 178 ft. "ahead of the air." If this charge can be sustained it is a serious matter, since in that case the company would have acted in direct violation of the law.

From various other sources reports come that after the first explosion the coroner's jury pronounced the company blameless without giving an opinion as to what caused the disaster; further assertions are made that the mining department did not make a report during the interval between the first and second explosions.

We have stated so often that the coroner's investigations of coal-mine explosions are valueless, furnishing only a pretense that the law prevails, that a repetition of our views ought to be unnecessary. During recent years all such inquiries have only entailed the useless expenditure of public money in the observance of a prescribed form. Solemnity has prevailed, but sincerity has been absent. There can be no fair trial without a prosecution.

The Rights of Stockholders

The well known gold mining company of California, Oroville Dredging, organized and originally owned by Americans, is being converted into a British corporation. English investors have lately become the largest stockholders in the company and the chief market for the stock is in London, which, of course, is a good reason for the conversion of the company. Another reason was stated with incisive frankness at a recent stockholders' meeting by F. W. Baker, the chairman, who remarked "I think our method—if I may put it so without any disrespect to our American friends, who are in the habit of running companies quite successfully—of giving more information to shareholders than the American companies generally do, is one which would receive the support of shareholders here, and I think also of the American shareholders. I met one shareholder—an American shareholder on the register—who said that for three years he had not had a single notice or any information. There is no shareholder on this side who has not had all the information we have had from the property, and in the future you will get more information, and that more frequently."

W. P. Hammon, general manager of the company, was thereupon inspired to remark as follows: "Speaking of the information given out by the company to the English shareholders, I think it may be well for me to state that it has been our custom from the operating end of the business to report fully—weekly, monthly, quarterly and annually—to the eastern offices. I am referring to Boston and New York. Our central office was in Boston until July of the past year, when it was moved to New York. Why you have not received full information regularly, I cannot say. I am not responsible for that, because we have made our reports regu-

larly, and there is no reason why you should not have received them. If, as our chairman has stated, the property be transferred to an English company, no doubt you will receive information direct from the operating end of the business and have it regularly."

Here is the whole situation respecting the rights of stockholders to prompt and full information respecting their property boiled down in a most practical way. The directors of British companies recognize this right; the directors of American companies do not. (Of course, we are speaking generally, because there are some praiseworthy exceptions among American companies and condemnable exceptions among British.)

Several years ago there was a general awakening of conscience in London, inspired by the mining engineers. As the result of their efforts, British companies have acquired the habit not only of publishing full, frank and prompt reports, but also information as to cost of production, ore reserves, etc., which enables stockholders and investors to compute the actual value of their property. And, moreover, investors, with the aid of the reputable financial press, have learned how to do so. Sooner or later we shall come to this also in America. This subject is now under discussion by the Mining and Metallurgical Society of America. We have no doubt that good will result from its discussion.

The Zinc Ore Question

On Jan. 19 the U. S. Circuit Court of Appeals handed down an opinion affirming the judgment of the Circuit Court that imports of zinc ore into the United States are not dutiable under the terms of the Dingley act. This ought to settle the protracted litigation over this question. The first decision under the present tariff act was made in 1905. The Government did not appeal from this decision, but decided to start over again and make a new case. This has now been disposed of as stated above. Every decision, from first to last, has been in favor of the importers, and it seems fair that the Government should now announce that it is through litigating the matter. Instructions to collectors to observe the court decisions and to refund the duties levied and paid under protest are now in order.

The Incorporation of American Companies Operating in Mexico

The Mexican government has recently shown a desire that foreign companies operating in Mexico should incorporate under Mexican laws. In many cases this has already been partially accomplished by a double incorporation. On one hand a holding company is incorporated under the laws of the United States, the stock of which is distributed, and on the other hand the holding company owns too per cent. of the stock of a Mexican incorporation, the operating company, which carries forward the work of the organization in Mexico. In such a case the requirements of the Mexican government and the desire of the stockholders to possess American securities are both satisfied.

This double incorporation has some very decided advantages, but serious errors have also been made. In a recent case in northern Mexico the holding company, in order to borrow money, pledged the whole of the stock of its Mexican incorporation. It failed to repay the loan; foreclosure took place, and on investigation the American holders found that they owned nothing but some office furniture, and an insignificant amount of cash.

In a double incorporation of this kind it is desirable that the Mexican stock shall not be at the mercy of the directorate of the holding company, but that it shall only be subject to alienation by a substantial majority of the shareholders of the holding company, having full knowledge of the possible results of their course of action.
